Abstract

A setoid is a set together with a constructive representation of an equivalence relation on it. Here, we give category theoretic support to the notion. We first define a category **Setoid** and prove it is cartesian closed with coproducts. We then enrich it in the cartesian closed category **Equiv** of sets and classical equivalence relations, extend the above results, and prove that **Setoid** as an **Equiv**-enriched category has a relaxed form of equalisers. We then recall the definition of \mathcal{E} -category, generalising that of **Equiv**-enriched category, and show that **Setoid** as an \mathcal{E} -category has a relaxed form of coequalisers. In doing all this, we carefully compare our category theoretic constructs with Agda code for type-theoretic constructs on setoids.

Keywords: setoid, proof assistant, proof irrelevance, Cartesian closed category, coproduct, **Equiv**-category, **Equiv**-inserter, \mathcal{E} -category, \mathcal{E} -coinserter

1. Introduction

The notion of setoid, albeit with different nomenclature, was introduced by Bishop in his development of constructive mathematics [1]. The key difference between it and sets is that one does not have equality of elements of a setoid, the closest approximant to equality being given by a constructive

representation of an equivalence relation, that is, a family of sets indexed by elements of the setoid. The elements of the family can be regarded as *proof objects* of the relation: the relation is considered to hold if and only if the corresponding set in the family is inhabited. Over recent years, Bishop’s idea has been taken up in the field of theorem proving using proof assistants including Agda, Coq and Isabelle[2, 3, 4]. Here, we give analysis of the structure of setoids in terms of category theory based on naïve set theory.

The *ordinary* category of setoids and their morphisms is Cartesian closed, but it seems there is no equalisers and coequalisers; even if they do exist, it would be something strange that cannot be used in a straightforward way. So, we consider *enrichment* over **Equiv**. The **Equiv**-category of setoids does have **Equiv**-inserters, which are weaker notion of equalisers, and cotensors, but it still seems to lack coequalisers and any of its weaker form. We then study the \mathcal{E} -category of setoids. The \mathcal{E} -category **Setoid** does not only have Cartesian closed structure, \mathcal{E} -inserters and cotensors, but also \mathcal{E} -coinserters and tensors. These are enough to say that there always exist a *weak notion of limit* and colimit of arbitrary (small) diagram in the \mathcal{E} -category of setoids. In fact, we give an Agda code which claims the existence in the Appendix.

We adopt the usual semantic practice of modelling a type by a set and modelling a term in context by a function. The definition of setoid inherently involves a type **Set**, so we shall assume we have a model of set theory and, with mild overloading of notation, use **Set** to denote the set of small sets, equivalently a model of sets.

Having adopted those conventions, a setoid A , in classical set-theoretic terms, consists of:

- a set $|A|$
- a family \approx_A of sets indexed by $|A| \times |A|$ (We write $a_0 \approx_A a_1$ for the set indexed by (a_0, a_1) .)
- for each $a \in |A|$, an element $\text{refl}_A(a)$ of $a \approx_A a$
- for each pair (a_0, a_1) of elements of $|A|$, a function $\text{sym}_A(a_0, a_1): (a_0 \approx a_1) \longrightarrow (a_1 \approx a_0)$
- for each triple (a_0, a_1, a_2) of elements of $|A|$, a function $\text{trans}_A(a_0, a_1, a_2): (a_1 \approx a_2) \times (a_0 \approx a_1) \longrightarrow (a_0 \approx a_2)$

There is some choice about a natural notion of map between setoids, but one natural option, which we shall make, is that a morphism $f: A \rightarrow B$ consists of:

- a function $\text{fun}_f: |A| \rightarrow |B|$ together with
- for each pair (a_0, a_1) of elements of $|A|$, a function $\text{resp}_f: (a_0 \approx a_1) \rightarrow (\text{fun}_f(a_0) \approx \text{fun}_f(a_1))$.

These definitions can be described by the following Agda code.

```
record Setoid : Set1 where
  field
    carrier : Set
    _≈_ : carrier → carrier → Set
    refl : {x : carrier} → x ≈ x
    sym : {x y : carrier} → x ≈ y → y ≈ x
    trans : {x y z : carrier} → y ≈ z → x ≈ y → x ≈ z

record _≈>_ (A B : Setoid) : Set where
  open Setoid ; _≅_ = _≈_ A ; _≈_ = _≈_ B
  field
    fun : carrier A → carrier B
    resp : {a0 a1 : carrier A} → a0 ≅ a1 → fun a0 ≈ fun a1
```

The most striking fact about the definition of setoids is the absence of coherence axioms. In particular, the data for reflexivity, symmetry and transitivity are exactly data appropriate for the definition of a groupoid: if one added natural coherence axioms to the definition of setoid, one would in fact have the definition of a groupoid. A central idea in the definition of setoid is *not* to insist upon equality between proof objects. The result is that setoids behave quite differently to groupoids or categories.

The behaviour of setoids would be simpler if the sets $a_0 \approx a_1$ were degenerated into singletons or instances of the empty set. That would correspond to the study of the category **Equiv** of equivalence relations.

The implications of the lack of coherence axioms are profound. For instance, a morphism of setoids, in contrast to a functor, need not preserve the data for reflexivity or transitivity: it follows from the definition of functor that functors preserve n -fold composition for any natural number n , whereas,

in the absence of a coherence axiom for transitivity, that would not hold if one imposed the usual functoriality condition on a morphism of setoids. And although we will consider equivalences between morphisms of setoids, (cf. natural isomorphisms between functors), it does not make sense to impose a naturality condition on them as, again in the absence of a coherence axiom for transitivity, a composite of such natural transformations would not be natural.

Setoids and morphisms between them generate a category **Setoid**. The lack of a requirement that the reflexivity, symmetry and transitivity data is preserved by a morphism of setoids impacts on the structure of the category **Setoid**. If such axioms were imposed on morphisms, the category **Setoid** would be locally finitely presentable, hence complete and cocomplete. But in fact **Setoid** seems not to have equalisers, although it does have products and is Cartesian closed.

We will duly study the structure of the category **Setoid** in this paper, in particular proving that it has products and coproducts and is Cartesian closed: the latter is quite complex. But in theorem proving practice, this category is not of interest per se: constructively, one cannot assert that parallel morphisms $f, g: A \longrightarrow B$ are equal; one can only assert that for each a in $|A|$, the set $f(a) \approx_B g(a)$ is inhabited, i.e., is non-empty. We extend **Setoid** to provide semantics to express the fact of two morphisms of setoids being equivalent, but not necessarily equal.

In order to provide such structure, we extend **Setoid** with the canonical structure of an **Equiv**-enriched category, **Equiv** being Cartesian closed. We induce an **Equiv**-enrichment of **Setoid** from the canonical **Equiv**-enrichment of **Equiv**. Cartesian closedness and coproducts extend from **Setoid** as an ordinary category to **Setoid** as an **Equiv**-enriched category. We further prove that **Setoid** as an **Equiv**-enriched category has a relaxed form of equaliser that we call an **Equiv**-inserter, cf. [5].

We make one further step. **Equiv**-categories have underlying ordinary categories, thus have strict associativity of morphisms. And the structures one considers on **Equiv**-categories, such as **Equiv**-products and **Equiv**-closedness reflect that strictness. But constructively, setoids do not have such strictness. We take advantage of that to prove the existence of further constructions on setoids, such as a relaxed notion of coequaliser that we call an \mathcal{E} -coinserter. **Equiv**-products are *a fortiori* \mathcal{E} -products, etc.

The central idea here is that every **Equiv**-category is an \mathcal{E} -category, as we shall discuss. In fact, we show that an **Equiv**-category is precisely a

strict \mathcal{E} -category, **Equiv**-categories being to \mathcal{E} -categories as 2-categories are to bicategories. It is **Setoid** as an \mathcal{E} -category about which the type-theoretic theorems and proofs about setoids hold.

This paper is organised as follows. In Section 2, the construction of the ordinary category **Equiv** of equivalence relations is introduced and its completeness, cocompleteness and Cartesian closedness are proved. This Cartesian closed category is important as a category over which **Setoid** will be enriched. In Section 3, we introduce another ordinary category **Setoid** of setoids and show that it is Cartesian closed and has coproducts. In Section 4, we introduce the notion of **Equiv**-enriched categories with an elementary description; **Equiv** is enriched to **Equiv**-enriched category **Equiv**. We extend the ordinary category **Setoid** to the **Equiv**-enriched category **Setoid** and study its structure in Section 5. The notion of \mathcal{E} -category is introduced in Section 6 and the structure of the specific \mathcal{E} -category **Setoid** is studied in Section 7. We conclude in Section 8. In Appendix A, we attach Agda code for setoids and the constructions in the \mathcal{E} -category **Setoid** studied in this paper.

Related work

The notion of setoids as presented above is folklore in theorem proving and its use can be traced back at least to Peter Aczel’s unpublished report [6]. Čubrić, Dybjer and Scott [7] introduced \mathcal{P} -categories, which can be obtained by replacing equivalence relations in \mathcal{E} -categories by partial equivalence relations. The first author studied \mathcal{E} -categories in connection with bicategories in [8], where the \mathcal{E} -equivalence of \mathcal{E} -categories and strict \mathcal{E} -categories is essentially but only implicitly described. Wilander defined a notion of \mathcal{E} -bicategory and studied an \mathcal{E} -bicategory of \mathcal{E} -categories, in particular Setoids [9, 10, 11, 12]. However, his definitions are given in terms of constructive type theory, whereas ours are given in terms of naïve set theory. We then use the set theoretic notions to study setoids described in constructive type theory.

There has been considerable work on constructive mathematics from a category theoretic perspective, in particular using techniques derived from topos theory and related to taking the exact completion of **Set** [13, 14, 15, 16, 17, 18].

2. The category **Equiv** of equivalence relations

A set with an equivalence relation is directly and naturally modelled by the following category **Equiv**.

Construction 1. The category **Equiv** consists of the following data.

- Objects are pairs $A = (|A|, \equiv_A)$ of a small set $|A|$ and an equivalence relation \equiv_A on it.
- Morphisms from A to B are functions from $|A|$ to $|B|$ that respect the equivalence relation, i.e., functions $f: |A| \rightarrow |B|$ such that $f(a_0) \equiv_B f(a_1)$ whenever $a_0 \equiv_A a_1$.
- Composition is given by composition of functions.
- Identities are identity functions.

These data satisfy the conditions for a category.

We shall call an object of **Equiv** an *equivalence relation*.

Theorem 2. *Equiv is complete and cocomplete.*

Proof. A product diagram in **Equiv** for a family $A = (A_i \mid i \in I)$ is given pointwise by

$$(P \xrightarrow{\pi_i} A_i \mid i \in I),$$

where $|P| \xrightarrow{\pi_i} |A_i|$ is the product diagram in **Set** and \equiv_P is given by $p \equiv_P p'$ if and only if $\pi_i(p) \equiv_{A_i} \pi_i(p')$ for all $i \in I$. Each π_i evidently respects the equivalence relations, so is a morphism in **Equiv**. The universal property holds because it is a product cone in **Set**.

An equaliser for a parallel pair of morphisms $f, g: A \rightarrow B$ in **Equiv** is given by

$$E \xrightarrow{e} A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B$$

where $|E| \xrightarrow{e} |A| \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} |B|$ is the equaliser diagram in **Set** and \equiv_E is defined by $x \equiv_E y$ if and only if $e(x) \equiv_A e(y)$. This clearly makes e a morphism in **Equiv**, and the universal property holds because the above is an equaliser diagram in **Set**.

A coproduct of $(A_i \mid i \in I)$ is also given pointwise. Let $|C|$ be the disjoint union of sets:

$$|C| \stackrel{\text{def}}{=} \coprod \{|A_i| \mid i \in I\}$$

and define \equiv_C by

$$\equiv_C \stackrel{\text{def}}{=} \coprod \{\equiv_{A_i} \mid i \in I\}$$

Clearly \equiv_C is an equivalence relation on C and each injection $\iota_i: |A_i| \hookrightarrow |C|$ respects the equivalence relation, so is a morphism in **Equiv**. It is routine to verify that $(\iota_i: A_i \rightarrow C \mid i \in I)$ is a coproduct diagram in **Equiv**.

Finally, a coequaliser of a pair of parallel morphisms $f, g: A \rightarrow B$ is given as follows. Define the set $|\text{Coeq}|$ so that $|A| \begin{smallmatrix} \xrightarrow{f} \\ \xrightarrow{g} \end{smallmatrix} |B| \xrightarrow{\text{coeq}} |\text{Coeq}|$ is the coequaliser in **Set**.

A binary relation \equiv_{Coeq} is defined by the transitive closure of the image of \equiv_B under coeq . It is an equivalence relation: reflexivity and symmetry follow from surjectivity of coeq . Therefore $\text{Coeq} = (|\text{Coeq}|, \equiv_{\text{Coeq}})$ is an object and coeq is a morphism of **Equiv**. It is routine to verify the universal property. \square

Theorem 3. *Equiv is Cartesian closed.*

Proof. Given two objects B and C of **Equiv**, the exponential $[B, C]$ is given by the set of functions $f: |B| \rightarrow |C|$ such that $b_0 \equiv_B b_1$ implies $f(b_0) \equiv_C f(b_1)$, and with equivalence relation given by $f \equiv_{[B, C]} g$ if for all $b \in B$, one has $f(b) \equiv_C g(b)$. The counit $\varepsilon \in \mathbf{Equiv}([B, C] \times B, C)$ sends (f, b) to $f(b)$; to see it is a morphism of **Equiv**, assume $f \equiv_{[B, C]} f'$ and $b \equiv_B b'$. Then $\varepsilon(f, b) = f(b) \equiv_C f'(b) \equiv_C f'(b') = \varepsilon(f', b')$, as required.

To show the universal property, let $A, B, C \in \text{ob}(\mathbf{Equiv})$ and $f \in \mathbf{Equiv}(A \times B, C)$. The currying operator in **Set** maps f to $\bar{f}: |A| \ni a \mapsto (\lambda b. f(a, b)) \in (|B| \rightarrow |C|)$, where $(|B| \rightarrow |C|)$ is the set of functions from $|B|$ to $|C|$. We first wish to show $\bar{f}(a) \in |[B, C]|$, for all $a \in |A|$. But if $b \equiv_B b'$, then $\bar{f}(a)(b) = f(a, b) \equiv_C f(a, b') = \bar{f}(a)(b')$ because f respects the equivalence relation. It is obvious that \bar{f} is the unique function that makes the following triangle commute.

$$\begin{array}{ccc} & A \times B & \\ & \swarrow \bar{f} \times \text{id}_B & \downarrow f \\ [B, C] \times B & \xrightarrow{\varepsilon} & C \end{array}$$

It remains to show $\bar{f} \in \mathbf{Equiv}(A, [B, C])$, that is, it is a morphism in \mathbf{Equiv} . But if $a \equiv_A a'$, $\bar{f}(a) = \lambda b. f(a, b) \equiv_{[B, C]} \lambda b. f(a', b) = \bar{f}(a')$ as $f(a, b) \equiv_{[B, C]} f(a', b)$ for all $b \in |B|$. \square

3. The category **Setoid** of setoids

A setoid is a constructive representation of an equivalence relation. We can study them in classical terms as follows.

Construction 4. The following data form a category, which we call **Setoid**.

- Objects are setoids as defined in the Introduction.
- For setoids A, B , $\mathbf{Setoid}(A, B)$ is the set of all morphisms from A to B , also as defined in the Introduction.
- For setoids A, B and C and morphisms $f: A \rightarrow B$ and $g: B \rightarrow C$, the morphism $g \circ f: A \rightarrow C$ is defined to be the pair of the composite $\text{fun}_g \circ \text{fun}_f: |A| \rightarrow |C|$ and, for each $a_0, a_1 \in |A|$, the composite $\text{resp}_g \circ \text{resp}_f$.
- For a setoid A , id_A is the pair of the identity function on $|A|$ and, for each $a_0, a_1 \in |A|$, the identity function on $a_0 \approx_A a_1$.

Setoid is equivalent to a full subcategory of the functor category from the pair of parallel arrows to \mathbf{Set} . It is not reflective as equalisers in **Setoid** are not given pointwise. We will not develop that approach to **Setoid** in this paper.

The equality between elements of homsets is referred to in these conditions, but such equalities are not available in proof assistants based on constructive type theory, such as Agda. Despite that, the structure of the category **Setoid** is studied in the rest of this section.

Theorem 5. *Setoid has all products and coproducts.*

Proof. We first construct binary products in **Setoid**, but the product of an arbitrary number of object is constructed similarly. Let A, B be setoids. We define the setoid $A \times B$ by

- $|A \times B| = |A| \times |B|$
- $(a, b) \approx_{A \times B} (a', b') = (a \approx_A a') \times (b \approx_B b')$

- $\text{refl}_{A \times B}((a, b)) = (\text{refl}_A(a), \text{refl}_B(b))$
- $\text{sym}_{A \times B}((a, b), (a', b')) = \text{sym}_A(a, a') \times \text{sym}_B(b, b')$
which is a function from $(a \approx_A a') \times (b \approx_B b')$ to $(a' \approx_A a) \times (b' \approx_B b)$.
- $\text{trans}_{A \times B}((a, b), (a', b'), (a'', b'')) = \text{trans}_A(a, a', a'') \times \text{trans}_B(b, b', b'')$,
a function from $((a' \approx_A a'') \times (a \approx_A a')) \times ((b' \approx_B b'') \times (b \approx_B b'))$ to $(a \approx_A a'') \times (b \approx_B b'')$.

The projection $\text{proj}_0 \in \text{Setoid}(A \times B, A)$ is defined as follows.

- $\text{fun}_{\text{proj}_0} \stackrel{\text{def}}{=} \pi_0$, where π_0 is the projection function from $|A| \times |B|$ to $|A|$.
- $\text{resp}_{\text{proj}_0} \stackrel{\text{def}}{=} \pi_0$, where π_0 is the projection function from $(a \approx_A a') \times (b \approx_B b')$ to $(a \approx_A a')$.

The other projection $\text{proj}_1: A \times B \rightarrow B$ is defined symmetrically.

To show the universal property, let $A \xleftarrow{f_0} C \xrightarrow{f_1} B$ be a cone on A and B . Then we can define $\langle f_0, f_1 \rangle: C \rightarrow A \times B$ by $\text{fun}_{\langle f_0, f_1 \rangle}(c) = (f_0(c), f_1(c))$ and $\text{resp}_{\langle f_0, f_1 \rangle} = (\text{resp}_{f_0}, \text{resp}_{f_1})$.

$$\begin{array}{ccccc}
 & & C & & \\
 & \swarrow f_0 & \vdots & \searrow f_1 & \\
 & & \langle f_0, f_1 \rangle & & \\
 & & \downarrow & & \\
 A & \xleftarrow{\text{proj}_0} & A \times B & \xrightarrow{\text{proj}_1} & B
 \end{array}$$

The above diagram commutes because $(\text{fun}_{\text{proj}_i} \circ \text{fun}_{\langle f_0, f_1 \rangle})(c) = \text{fun}_{\text{proj}_i}(f_0(c), f_1(c)) = f_i(c)$ for $i = 0, 1$, and $\text{resp}_{\text{proj}_i} \circ \text{resp}_{\langle f_0, f_1 \rangle} = \text{resp}_{\text{proj}_i}$ similarly. It is obvious that $\langle f_0, f_1 \rangle$ is the only such.

A coproduct of A_0 and A_1 is also given pointwise. We define the setoid $A_0 + A_1$ as follows.

- $|A_0 + A_1| \stackrel{\text{def}}{=} |A_0| + |A_1|$.
Let $\iota_i: |A_i| \rightarrow |A_0 + A_1|$ be the injection morphism.
- $\approx_{A_0 + A_1} = \approx_{A_0} + \approx_{A_1}$
- $\text{refl}_{A_0 + A_1}(i, a) \stackrel{\text{def}}{=} (i, \text{refl}_{A_i}(a))$.

- $\text{sym}_{A_0+A_1}((i, a), (j, a'))((m, p)) \stackrel{\text{def}}{=} (i, \text{sym}_{A_i}(a, a', p))$.
 (m, p) is an element of $(i, a) \approx_{A_m} (j, a')$, so i, j and m must all be equal.
Then $\text{sym}_{A_0+A_1}((i, a), (i, a'))((i, p))$ is the pair of i and $\text{sym}_{A_i}(a, a')(p)$.
- $\text{trans}_{A_0+A_1}((i, a), (j, a'), (k, a''))((m, p), (n, q)) = (i, \text{trans}_{A_i}(a, a', a'')(p, q))$.
 (m, p) is an element of $(j, a') \approx_{A_m} (k, a'')$, so j, k and m must be equal;
similarly, $(n, q) \in ((i, a) \approx_{a_n} (j, a'))$, so $i = j = n$. Therefore $i = j = k = m = n$. The element $\text{trans}_{A_0+A_1}((i, a), (i, a'), (i, a''))((i, p), (i, q))$ is the pair of i and $\text{trans}_{A_i}(a, a, a'')(p, q)$.

The injection $\iota_i \in \text{Setoid}(A_i, A_0 + A_1)$, ($i = 0, 1$) is defined as follows.

- $\text{fun}_{\iota_i}: |A_i| \longrightarrow |A_0 + A_1|$ is defined by $\text{fun}_{\iota_i}(a) \stackrel{\text{def}}{=} (i, a)$.
- For $a, a' \in A_i$, $\text{resp}_{\iota_i}: a \approx_{A_i} a' \longrightarrow \text{fun}_{A_i}(a) \approx_{A_0+A_1} \text{fun}_{A_i}(a')$ is defined by $\text{resp}_{\iota_i}(p) = (i, p)$

Then the bottom line in the diagram below is a coproduct diagram in **Setoid**.

$$\begin{array}{ccccc}
& & C & & \\
& \nearrow f_0 & \uparrow \hat{\wedge} & \nwarrow f_1 & \\
& & [f_0, f_1] & & \\
& & \vdots & & \\
A_0 & \xrightarrow{\quad} & A_0 + A_1 & \xleftarrow{\quad} & A_1 \\
& \searrow \iota_0 & & \swarrow \iota_1 &
\end{array}$$

To show it, let C be an arbitrary object and $f_0 \in \text{Setoid}(A_0, C)$, $f_1 \in \text{Setoid}(A_1, C)$ be arbitrary morphisms in **Setoid**. Define $[f_0, f_1] \in \text{Setoid}(A_0 + A_1, C)$ as follows.

- $\text{fun}_{[f_0, f_1]}((i, a)) \stackrel{\text{def}}{=} \text{fun}_{f_i}(a)$
- For elements a_i and a'_i of $|A_i|$ and p of $a_i \approx_{A_i} a'_i$, $\text{resp}_{[f_0, f_1]}((i, p)) \stackrel{\text{def}}{=} \text{resp}_{f_i}(p)$.

Both triangles commute: the left triangle commutes because $(\text{fun}_{[f_0, f_1]} \circ \text{fun}_{\iota_0})(a) = \text{fun}_{[f_0, f_1]}((0, a)) = \text{fun}_{f_0}(a)$ for all a in $|A_0|$, and $(\text{resp}_{[f_0, f_1]} \circ \text{resp}_{\iota_0})(p) = \text{resp}_{f_0}(p)$ and the right triangle commutes similarly.

To see the uniqueness, let $h \in \text{Setoid}(A_0 + A_1, C)$ be a morphism such that $h \circ \iota_i = f_i$ for $i = 0$ and 1 , and we shall show $h = [f_0, f_1]$. The uniqueness of the **fun** part is obvious because it is a coproduct diagram in **Set**. To show the uniqueness of the **resp** part, let x and x' be elements of $|A_0 + A_1|$ and p be an

element of $x \approx_{A_0+A_1} x'$. Because $x \approx_{A_0+A_1} x'$ is inhabitant, x , x' and p are of the form (i, a) , (i, a') and (i, q) for the same i , $a, a' \in |A_i|$ and $q \in a \approx_{A_i}$. So, $\text{resp}_h(p) = \text{resp}_h((i, q)) = \text{resp}_h(\iota_i(q)) = \text{resp}_{f_i}(q) = \text{resp}_{[f_0, f_1]}(\iota_i(q)) = \text{resp}_{[f_0, f_1]}(p)$, but p is arbitrary, so $\text{resp}_h = \text{resp}_{[f_0, f_1]}$, as required. \square

Given setoids A and B , an element of the exponential $[A, B]$ is *not* given by a morphism of setoids from A to B . Rather, it is given by a function $f: |A| \rightarrow |B|$ for which, for all a_0 and a_1 in $|A|$, there *exists* a function φ from $a_0 \approx_A a_1$ to $f(a_0) \approx_B f(a_1)$. So, rather than being a morphism of setoids, an element of the exponential is a morphism of the induced objects of **Equiv** that is introduced in Section 2.

Theorem 6. *Setoid is Cartesian closed.*

Proof. Leaving the reflexivity, symmetry and transitivity data implicit, given setoids A , B and C , a morphism f of setoids from $A \times B$ to C consists of a function $\text{fun}_f: |A| \times |B| \rightarrow |C|$ together with, for all $a, a' \in |A|$ and all $b, b' \in |B|$, a function

$$\text{resp}_f: (a \approx_A a') \times (b \approx_B b') \rightarrow f(a, b) \approx_C f(a', b')$$

These data can be re-expressed as functions $\text{fun}_h: |A| \rightarrow (|B| \rightarrow |C|)$ and

$$\text{resp}_h: (a \approx_A a') \rightarrow ((b \approx_B b') \rightarrow (h(a)(b) \approx_C h(a')(b')))$$

So data for a *potential* exponential $[B, C]$ is given by the set $(|B| \rightarrow |C|)$ of all functions $k: |B| \rightarrow |C|$, with $k \approx_{[B, C]} k'$ given by the product over all $b, b' \in |B|$ of $((b \approx_B b') \rightarrow (k(b) \approx_C k'(b')))$.

However, this data does not satisfy the reflexivity axiom in the definition of setoid: for a setoid, for each $k \in [B, C]$, the set $k \approx_{[B, C]} k$ must be non-empty. That need not be true for an arbitrary function $k: |B| \rightarrow |C|$, but it is true for any function k that underlies a morphism of setoids from B to C .

In fact, given a morphism of setoids f from $A \times B$ to C , for any $a \in |A|$, the function $\text{fun}_f(a, -): |B| \rightarrow |C|$ does underlie a morphism of setoids.

So an exponential $[B, C]$ does exist: an element is a function $k: |B| \rightarrow |C|$ for which, for every $b, b' \in |B|$, there exists a function from $b \approx_B b'$ to $k(b) \approx_C k(b')$, with $\approx_{[B, C]}$ defined as above.

It is routine to verify that this gives data for a setoid; and its universal property holds by construction. \square

From the perspective of setoids as a type-theoretic construct, the closed structure of the category **Setoid** is remarkable: the elements of the exponential necessarily involve an existence condition because of the requirement of existence of reflexivity, but the family is inherently constructive.

Moreover, $k \approx_{[B,C]} k'$ is given in a specific way: it assigns to each pair b, b' of elements of $|B|$, a function from $b \approx_B b'$ to $k(b) \approx_C k'(b')$, rather than assigning, to each single element $b \in |B|$, a function from $b \approx_B b$ to $k(b) \approx_C k'(b)$. These are not interchangeable: the replacement of the first by the second does not describe the closed structure of the category **Setoid**.

However, up to equivalence, they do agree. So, when we consider **Setoid** as an \mathcal{E} -category in Section 6, its closed structure as an ordinary category is also \mathcal{E} -closed structure, but \mathcal{E} -closed structure is unique only up to equivalence, whereas ordinary closed structure is unique up to isomorphism. So in **Setoid** as an \mathcal{E} -category, the closed structure as we have defined it and the alternative above both act as \mathcal{E} -closed structures.

A morphism in **Setoid** from 1 to an exponential $[A, B]$ consists of a function from the set 1 to the carrier of the exponential, i.e., a function $\text{fun}_f : |A| \rightarrow |B|$ for which there *exist* functions from $a \approx_A a'$ to $\text{fun}_f(a) \approx_B \text{fun}_f(a')$, together with a function from 1 to the set of families of functions, of the form $\text{resp}_f : a \approx_A a' \rightarrow \text{fun}_f(a) \approx_B \text{fun}_f(a')$. The existence clause is therefore redundant.

4. Equiv-enriched categories

Categories can be *enriched* over **Equiv**, as the latter is Cartesian closed. The definition of **Equiv**-enriched category, or simply **Equiv**-category, is only an instance of \mathcal{V} -enriched category for symmetric monoidal \mathcal{V} , but we explicitly state it for the purpose of self-containedness.

Definition 7. An **Equiv**-enriched category **C** consists of the following data:

- a set $\text{ob}(\mathbf{C})$, elements of which are called objects of **C**.
- for each $C, C' \in \text{ob}(\mathbf{C})$, an object $\mathbf{C}(C, C')$ of **Equiv**.
- for each $C, C', C'' \in \text{ob}(\mathbf{C})$, a function $\square : |\mathbf{C}(C', C'') \times \mathbf{C}(C, C')| \rightarrow |\mathbf{C}(C, C'')|$ such that $(g \square f) \equiv_{\mathbf{C}(C, C'')} (g' \square f')$ whenever $g \equiv_{\mathbf{C}(C', C'')} g'$ and $f \equiv_{\mathbf{C}(C, C')} f'$.
- for each $C \in \text{ob}(\mathbf{C})$, an object $\text{id}_C \in |\mathbf{C}(C, C)|$

These data are subject to the following three conditions.

- For $C, C', C'', C''' \in \text{ob}(\mathbf{C})$ and $f \in |\mathbf{C}(C, C')|$, $g \in |\mathbf{C}(C', C'')|$, $h \in |\mathbf{C}(C'', C''')|$,

$$h \square (g \square f) = (h \square g) \square f.$$

- For $C, C' \in \text{ob}(\mathbf{C})$ and $f \in |\mathbf{C}(C, C')|$,

$$f \square \text{id}_C = f.$$

- For $C, C' \in \text{ob}(\mathbf{C})$ and $f \in |\mathbf{C}(C, C')|$,

$$\text{id}_{C'} \square f = f.$$

So, **Equiv**-categories have hom-equivalence-classes rather than homsets. Another way of looking at it is that an equivalence relation is defined for parallel pairs of morphisms (elements of the carrier of homobjects).

Given an **Equiv**-category \mathbf{C} , its *underlying category* \mathbf{C}_\circ is defined as follows. Its objects are the same as the objects of \mathbf{C} . The homset $\mathbf{C}_\circ(x, y)$ is the carrier set $|\mathbf{C}(x, y)|$ of the homobject for these objects. The composition and identity of the underlying category are the same as those of \mathbf{C} .

Let \mathbf{C} be a category. If an **Equiv**-category is defined so that its underlying category coincides with \mathbf{C} , we say \mathbf{C} is *enriched* to it. In order to enrich a category we have only to give an equivalence relation on each homset such that the composition respects those equivalence relations.

Construction 8. The category **Equiv** is enriched to the **Equiv**-enriched category **Equiv**. The equivalence relation on each homset is defined so that $f \equiv g$ if and only if $f(a) \equiv g(a)$ for all a .

To see the composition preserves these equivalence relations, let $f \equiv g$ and $f' \equiv g'$, with domains and codomains agreeing. Then for all a , $f'f(a) \equiv f'g(a) \equiv g'g(a)$, the first of these holding because $f \equiv g$ and because f' is a morphism of equivalence relations, with the latter holding because $f' \equiv g'$.

The general theory of enriched categories, or more specifically that of 2-categories, determines definitions of **Equiv**-functor, **Equiv**-natural transformation, **Equiv**-enriched adjoint, **Equiv**-products, **Equiv**-coproducts, **Equiv**-cotensors, and **Equiv**-closedness [5, 19]. We also adopt the notion of inserter from the theory of 2-categories [5]. We can express these definitions in elementary terms of **Equiv**-categories.

For example, given **Equiv**-enriched categories \mathbf{C} and \mathbf{D} , an **Equiv-functor** from \mathbf{C} to \mathbf{D} is an ordinary functor $H: \mathbf{C}_\circ \rightarrow \mathbf{D}_\circ$ such that if $f \equiv_{\mathbf{C}(c,c')} f'$, then $H(f) \equiv_{\mathbf{D}(H(c),H(c'))} H(f')$. Just as \mathbf{C} has an ordinary underlying category \mathbf{C}_\circ , an **Equiv-functor** H has an underlying ordinary functor H_\circ : it has exactly the same data as H .

An **Equiv-enriched natural transformation** from H to K is exactly an ordinary natural transformation from H_\circ to K_\circ .

Equiv-categories, **Equiv**-functors and **Equiv**-natural transformations form a 2-category, as is the case for enriched categories in general, and that determines a definition of **Equiv**-enriched adjoint. In elementary terms, an **Equiv-functor** $H: \mathbf{C} \rightarrow \mathbf{D}$ has an **Equiv**-enriched left adjoint if the ordinary functor $H_\circ: \mathbf{C}_\circ \rightarrow \mathbf{D}_\circ$ has an ordinary left adjoint L subject to the additional condition that the bijections

$$\mathbf{C}_\circ(L(d), c) \cong \mathbf{D}_\circ(d, H(c))$$

respect the equivalence relations on $\mathbf{C}(L(d), c)$ and $\mathbf{D}(d, H(c))$.

Given objects a and b of an **Equiv**-enriched category \mathbf{C} , an **Equiv-product** of a and b is a product $a \times b$ in \mathbf{C}_\circ subject to one additional property: if $f \equiv_{\mathbf{C}(c,a)} f'$ and $g \equiv_{\mathbf{C}(c,b)} g'$, then $(f, g) \equiv_{\mathbf{C}(c,a \times b)} (f', g')$.

Equiv-coproduct is the dual notion to **Equiv-product**.

The notion of cotensor appears generally in enriched category theory, but not often in ordinary category theory, so we spell out its definition in detail here.

Definition 9. Given an equivalence relation X and an object a of an **Equiv**-category \mathbf{C} , an **Equiv-cotensor** a^X of a by X is an object with the universal property that, for any object b of \mathbf{C} , there is a natural bijection between the set of morphisms of equivalence relations

$$X \rightarrow \mathbf{C}(b, a)$$

and the set of morphisms in \mathbf{C}

$$b \rightarrow a^X$$

with the bijection respecting equivalent morphisms.

Definition 10. An **Equiv-serter** of morphisms $f, g: a \rightarrow b$ in an **Equiv**-category \mathbf{C} is an object e together with a morphism $\iota: E \rightarrow A$ such that

$f \circ \iota$ is equivalent to $g \circ \iota$, universally so, i.e., for any object c and morphism $\gamma: c \rightarrow a$ such that $f \circ \gamma \equiv_{C(c,b)} g \circ \gamma$, there is a unique morphism $\bar{\gamma}: c \rightarrow e$ such that $\iota \circ \bar{\gamma} = \gamma$. Moreover, $\gamma \equiv_{C(c,a)} \gamma'$ implies $\bar{\gamma} \equiv_{C(c,e)} \bar{\gamma}'$.

An **Equiv**-category \mathbf{C} with finite products is called **Equiv-closed** if for every object a of \mathbf{C} , the **Equiv**-functor $(- \times a): \mathbf{C} \rightarrow \mathbf{C}$ has an **Equiv**-enriched right adjoint.

5. The **Equiv**-category **Setoid** of setoids

Although setoids and equivalence relations are different, the former are often considered to be a representation of the latter in type theoretic practice. The construction of the following reflection explains it.

Proposition 11. *There is an evident inclusion $J: \mathbf{Equiv} \rightarrow \mathbf{Setoid}$, and it has a left adjoint F that sends a setoid A to an equivalence relation $(|A|, \equiv_A)$ where $a \equiv_A a'$ if and only if $(\exists p) p \in (a \approx_A a')$.*

$$F \dashv J: \mathbf{Equiv} \hookrightarrow \mathbf{Setoid}$$

The left adjoint F corresponds to “degenerating” the proofs of equivalence. We use F to give the category **Setoid** a canonical **Equiv**-enrichment as follows.

Definition 12. The following data defines an **Equiv**-category **Setoid**.

- The set of objects is the set of setoids.
- For setoids A, B , $\mathbf{Setoid}(A, B)$ is the equivalence relation on the set of setoid morphisms from A to B , where two morphisms f and g are equivalent if and only if $F(f)$ and $F(g)$ are equivalent in $\mathbf{Equiv}(F(f), F(g))$.
- For all setoids A, B and C , the setoid morphism $\square_{ABC}: \mathbf{Setoid}(B, C) \times \mathbf{Setoid}(A, B) \rightarrow \mathbf{Setoid}(A, C)$ is defined by $f \square g = f \circ g$, where \circ is the composition in the category **Setoid**. Observe that if $f \equiv f'$ and $g \equiv g'$, then $f \square g \equiv f' \square g'$.

The ordinary category **Setoid** has products and coproducts; they enrich to **Equiv**, i.e., the same constructions satisfy the properties required to be **Equiv**-products and **Equiv**-coproducts.

The closed structure of **Setoid** as an ordinary category extends to closed structure of **Setoid** as an **Equiv**-category: for any setoid A , the ordinary functor $(-\times A): \mathbf{Setoid} \rightarrow \mathbf{Setoid}$ extends to an **Equiv**-functor, i.e., it respects equivalences between morphisms in **Setoid**, and its ordinary right adjoint satisfies the property required to be an **Equiv**-enriched right adjoint.

5.1. Inserters in the **Equiv**-category **Setoid**

Equalisers seem not to exist in **Setoid** as an ordinary category: if they do, they certainly are not given pointwise. So that *a fortiori* is also true of **Setoid** as an **Equiv**-enriched category. Similarly, coequalisers do not seem to exist in **Setoid** as an ordinary category, so, *a fortiori*, seem not to exist in **Setoid** as an **Equiv**-category. Nevertheless, **Setoid** does have **Equiv**-inserters (Definition 10).

Theorem 13. *All parallel pairs of morphisms in the **Equiv**-category **Setoid** have **Equiv**-inserters.*

Proof. Given $f, g: A \rightarrow B$ in **Setoid**, let E be the set of elements a of $|A|$ for which $f(a) \approx_B g(a)$ is inhabited, and define \approx_E by restriction of \approx_A . Define $e: E \rightarrow A$ by inclusion.

It is routine to verify that this satisfies the axsa for an **Equiv**-inserter. \square

Equiv-inserters are remarkably non-constructive, and in that specific sense, they differ from iso-inserters in the theory of 2-categories. Their non-constructiveness means that the construction of E in Theorem 13 does not directly correspond to Agda code. For the latter, one wants not just an element a of $|A|$ for which $f(a) \approx_B g(a)$ is inhabited, but rather an element a together with an element of $f(a) \approx_B g(a)$, but such an object is not the **Equiv**-inserter, and it seems not to be a limit in the **Equiv**-category **Setoid**.

However, as we shall see, the definition of **Equiv**-inserter extends naturally to a definition of \mathcal{E} -inserter, for which one weakens the commutativity condition $e \circ \bar{x} = x$ to the condition that $e \circ \bar{x}$ is equivalent to x . Doing so means that \mathcal{E} -inserters are only defined by to equivalence, rather than up to isomorphism, upon which the natural Agda code does yield an \mathcal{E} -inserter, one that is equivalent to the canonical choice determined by the **Equiv**-inserter, which is, *a fortiori*, an \mathcal{E} -inserter.

The situation for coinserters is quite different. The **Equiv**-category **Setoid** seems not to have **Equiv**-coinserters, where the notion of coinsserter is dual to that of inserter. But it does have \mathcal{E} -coinserters and these agree with Agda code.

5.2. Cotensors in the Equiv-category **Setoid**

Theorem 14. *The Equiv-category **Setoid** has cotensors, given as follows. An element of $|B^X|$ is a function $h: |X| \rightarrow |B|$ such that if $x \equiv x'$, then $h(x) \approx_B h(x')$ is nonempty (inhabited). An element of $h \approx_{B^X} h'$ is given by an assignment, to each element x of $|X|$, of an element of $h(x) \approx_B h(x')$.*

Proof. A morphism of equivalence relations from X to **Setoid**(A, B) consists of a function $f: |X| \rightarrow |\mathbf{Setoid}(A, B)|$ such that if $x \equiv_X x'$, $f(x) \equiv_{\mathbf{Setoid}(A, B)} f(x')$, that is, such that for all $a \in |A|$, $f(x)(a) \approx_B f(x')(a)$ is inhabited.

To give such data is equivalent to giving a function $f: X \rightarrow [A, B]$ together with, for all $x \in |X|$, and for all $a, a' \in |A|$, a function $f_{\approx} : (a \approx_A a') \rightarrow (f(x)(a) \approx_B f(x)(a'))$.

Reorganising this data, and adding the condition on f as a morphism of equivalence relations, this is equivalent to giving a function $g: A \rightarrow [X, B]$ together with, for each $a, a' \in |A|$, and for each $x \in |X|$, a function $g_{\approx} : (a \approx_A a') \rightarrow g(a)(x) \approx_B g(a')(x)$ such that, for all $a \in |A|$, if $x \equiv x'$, then $g(a)(x) \approx_B g(a)(x')$.

Putting $g(a) = h$, this agrees with the construction in the statement of the proposition. The construction in the statement can routinely be checked to possess the requisite reflexivity, symmetry and transitivity data. \square

Cotensors bear close resemblance to the closed structure of **Setoid**. If one considers the equivalence relation X as a setoid, one in which each set in the family has either one element or none, the set B^X is exactly the set given by the closed structure of **Setoid**.

However, the associated families of sets $h \approx_{[X, B]} h'$ are subtly different. For cotensors, we can express an element of $h \approx_{[X, B]} h'$ as the assignment, to each element x of $|X|$, of a function from $x \approx x$ to $h(x) \approx_B h'(x)$. In contrast, for the closed structure, we required, for each pair (x, x') of elements of X , a function from $x \approx_X x'$ to $h(x) \approx_B h'(x')$.

Thus the closed structure and the cotensors, although closely related to each other, are not isomorphic. However, they are equivalent, i.e., there are morphisms in **Setoid** $r: B^X \rightarrow [X, B]$ and $s: [X, B] \rightarrow B^X$ for which the composite $r \circ s$ is equivalent to the identity morphism on $[X, B]$ and similarly for $s \circ r$: there are evident choices of such morphisms, the behaviour on carriers being the identity functions.

This means that, although the closed structure and cotensors of **Setoid** do not agree as **Equiv**-structures, they do agree as \mathcal{E} -structures, i.e., **Setoid**

is \mathcal{E} -closed and has \mathcal{E} -cotensors, and for any equivalence relation X seen as a setoid, the two \mathcal{E} -structures agree.

In stark contrast to this, it seems unlikely that **Setoid** as an **Equiv**-category has tensors, although it does have \mathcal{E} -tensors.

6. \mathcal{E} -categories

\mathcal{E} -categories naturally arise when categories are treated in constructive settings [20]. \mathcal{E} -categories are closely related to \mathcal{P} -categories, which also arise when categories are treated constructively. The definition of \mathcal{P} -category is obtained by replacing equivalence relations by partial equivalence relations in the definition of \mathcal{E} -category. \mathcal{P} -categories are studied in [7], but the authors did not always distinguish \mathcal{P} -categories from categories enriched over the Cartesian closed category of partial equivalence relations.

6.1. Basic definitions

Definition 15. An \mathcal{E} -category \mathbf{C} consists of the following data.

- a set $\text{ob}(\mathbf{C})$
- for each $x, y \in \text{ob}(\mathbf{C})$ an object $\mathbf{C}(x, y)$ of **Equiv**.
- for each $x, y, z \in \text{ob}(\mathbf{C})$, a morphism $\circ: \mathbf{C}(y, z) \times \mathbf{C}(x, y) \longrightarrow \mathbf{C}(x, z)$ in **Equiv**
- for each $x \in \text{ob}(\mathbf{C})$, an element id_x of $|\mathbf{C}(x, x)|$

These data are subject to the following conditions.

- for each $w, x, y, z \in \text{ob}(\mathbf{C})$, $f \in \mathbf{C}(y, z)$, $g \in \mathbf{C}(x, y)$ and $h \in \mathbf{C}(w, x)$, $(f \circ g) \circ h \equiv_{\mathbf{C}(w, z)} f \circ (g \circ h)$
- for each $x, y \in \text{ob}(\mathbf{C})$ and $f \in \mathbf{C}(x, y)$, $\text{id}_y \circ f \equiv_{\mathbf{C}(x, y)} f$ and $f \circ \text{id}_x \equiv_{\mathbf{C}(x, y)} f$.

Example 16. Every **Equiv**-category is an \mathcal{E} -category. Such an \mathcal{E} -category is called *strict* in [7]. **Setoid** is a strict \mathcal{E} -category, for instance.

The reason for considering \mathcal{E} -categories in addition to **Equiv**-categories is that the axioms for them are written only in terms of equivalence relations with equality of morphisms not appearing at all. Avoiding equality has a practical advantage in proof assistants based on constructive type theory. We emphasise that equality of morphisms is used in the axioms of categories and **Equiv**-categories and that is an obstacle to deal with them in those proof assistants.

\mathcal{E} -categories are special kinds of *bicategories* [21] where the homcategories are equivalence relations, because an equivalence relation is a groupoid each of whose homsets has at most one element. Because of this degeneracy, we do not need some coherence axioms for \mathcal{E} -categories that are necessary for bicategories. There is an analysis of \mathcal{E} -categories based on this observation [8].

\mathcal{E} -functors are a special case of pseudo-functors between bicategories.

Definition 17. Let \mathbf{A} and \mathbf{B} be \mathcal{E} -categories. An \mathcal{E} -functor F from \mathbf{A} to \mathbf{B} consists of the following data.

- A function $F_0: \text{ob}(\mathbf{A}) \longrightarrow \text{ob}(\mathbf{B})$.
- For each $x, y \in \text{ob}(\mathbf{A})$, a function $F_1(x, y): \mathbf{A}(x, y) \longrightarrow \mathbf{B}(F_0(x), F_0(y))$.

We often overload F_0 and F_1 and write F for them. These data are subject to the following conditions.

- For each $x, y, z \in \text{ob}(\mathbf{A})$, $f_0 \in |\mathbf{A}(y, z)|$ and $f_1 \in |\mathbf{A}(x, y)|$, $F(f_0 \circ f_1) \equiv F(f_0) \circ F(f_1)$.
- For each $x \in \text{ob}(\mathbf{A})$, $F(\text{id}_x) \equiv \text{id}_{F(x)}$.

Likewise, \mathcal{E} -natural transformations are defined as follows.

Definition 18. Let \mathbf{A} and \mathbf{B} be \mathcal{E} -categories and $F, G: \mathbf{A} \longrightarrow \mathbf{B}$ be \mathcal{E} -functors from \mathbf{A} to \mathbf{B} . An \mathcal{E} -natural transformation is a function which maps $x \in \text{ob}(\mathbf{A})$ to an element of $\mathbf{B}(F(x), G(x))$ subject to $G(f) \circ \alpha_x \equiv \alpha_y \circ F(f)$, for each $f \in \mathbf{A}(x, y)$.

The vertical and horizontal compositions of \mathcal{E} -natural transformations, as well as identity \mathcal{E} -natural transformations are defined as expected. Modification in \mathcal{E} -context becomes an equivalence between natural transformations.

Definition 19. Let \mathbf{A} and \mathbf{B} be \mathcal{E} -categories, $F, G: \mathbf{A} \longrightarrow \mathbf{B}$ be \mathcal{E} -functors. \mathcal{E} -natural transformations $\alpha, \beta: F \longrightarrow G: \mathbf{A} \longrightarrow \mathbf{B}$ are *isomorphic* if and only if $\alpha_x \equiv \beta_x$ for all $x \in \text{ob}(\mathbf{A})$.

Definition 20. Let \mathbf{A} and \mathbf{B} be \mathcal{E} -categories. The \mathcal{E} -functor \mathcal{E} -category², written $[\mathbf{A}, \mathbf{B}]$, consists of the following data.

- The set $\text{ob}([\mathbf{A}, \mathbf{B}])$ of objects is the set of \mathcal{E} -functors from \mathbf{A} to \mathbf{B} .
- For $F, G \in \text{ob}([\mathbf{A}, \mathbf{B}])$, $[\mathbf{A}, \mathbf{B}](F, G)$ consists of the set of \mathcal{E} -natural transformations from F to G and the equivalence of \mathcal{E} -natural transformations, as defined in Definition 19.
- The composition of morphisms is the vertical composition of \mathcal{E} -natural transformations.
- id is the identity \mathcal{E} -natural transformation.

If \mathbf{B} is strict, then $[\mathbf{A}, \mathbf{B}]$ is strict.

Following the practice for bicategories, we say two \mathcal{E} -categories \mathbf{A} and \mathbf{B} are \mathcal{E} -equivalent if there are \mathcal{E} -functors $H: \mathbf{A} \rightarrow \mathbf{B}$ and $K: \mathbf{B} \rightarrow \mathbf{A}$ such that $K \circ H$ is equivalent to the identity \mathcal{E} -functor on \mathbf{A} and $H \circ K$ is equivalent to the identity \mathcal{E} -functor on \mathbf{B} .

The following result is implicit in [8].

Theorem 21. *Every \mathcal{E} -category is \mathcal{E} -equivalent to an **Equiv**-category.*

Proof. There is a Yoneda embedding of any small \mathcal{E} -category \mathbf{A} into the \mathcal{E} -functor \mathcal{E} -category $[\mathbf{A}, \mathbf{Equiv}]$. The latter is a strict \mathcal{E} -category as **Equiv** is a strict \mathcal{E} -category. The Yoneda embedding is an equivalence on homs, so \mathbf{A} is \mathcal{E} -equivalent to a full sub- \mathcal{E} -category of $[\mathbf{A}, \mathbf{Equiv}]$, thus to a strict \mathcal{E} -category. \square

6.2. Structures on \mathcal{E} -categories

An object of **Equiv**, i.e., a set X together with an equivalence relation \equiv_X on it, may be seen as a category: X is the set of objects and $X(x_0, x_1)$ is 1 if $x_0 \equiv_X x_1$ and is otherwise 0. This construction extends to a functor $J: \mathbf{Equiv} \rightarrow \mathbf{Cat}$, which is fully faithful and has a left adjoint, thus exhibiting **Equiv** as a full reflective subcategory of **Cat**, as discussed in Proposition 11.

The functor J induces an inclusion of **Equiv-Cat** into the category of **Cat**-categories, i.e., into the category of 2-categories. So every **Equiv**-category can be seen as a 2-category.

²This term is introduced as the “ \mathcal{E} -version” of the notion of functor category. It does not mean any particular \mathcal{E} -functor that is called “ \mathcal{E} -category”.

Every \mathcal{E} -category can likewise be seen as a bicategory, as was central to [8]: the key idea of a bicategory as opposed to a 2-category is that composition of morphisms is transitive and has a unit only up to coherent isomorphism [7, 8]. The relationship between **Equiv**-categories and \mathcal{E} -categories is given by the relationship between 2-categories and bicategories.

There is an extensive literature about bicategorical limits, colimits and Cartesian closedness, including [22, 5]. So restriction from bicategories to \mathcal{E} -categories immediately yields a theory of limits, colimits and closedness for \mathcal{E} -categories.

We shall not spell out the bicategorical definitions as they involve coherence axioms, i.e., axioms that say which composites of two-dimensional isomorphisms are equal to each other, as those issues do not arise here. We simply remark that the limits, colimits, and closedness constructions we consider are all given by restriction of the well-established bicategorical constructs. The key constructs there are those of biproduct, biequaliser (equivalently bi-iso-inserter), and bicotensor and biclosedness. We refer to the restricted notions as \mathcal{E} -products, \mathcal{E} -inserters, \mathcal{E} -cotensors, their \mathcal{E} -duals, and \mathcal{E} -closedness.

We give the definition of a binary \mathcal{E} -product explicitly; an \mathcal{E} -product of any number $n \geq 0$ of objects is similar.

Definition 22. An \mathcal{E} -product of objects X and Y in an \mathcal{E} -category consists of an object $X \times Y$ and morphisms $\pi_X: X \times Y \rightarrow X$ and $\pi_Y: X \times Y \rightarrow Y$ such that for any object A and morphisms $f: A \rightarrow X$ and $g: A \rightarrow Y$, there is a morphism $h: A \rightarrow X \times Y$ such that $\pi_X h \equiv f$ and $\pi_Y h \equiv g$. Moreover, if $f \equiv f'$ and $g \equiv g'$, then $h \equiv h'$ for any such h and h' .

Definition 23. An \mathcal{E} -inserter of morphisms $f, g: X \rightarrow Y$ in an \mathcal{E} -category consists of an object $\text{Iso}(f, g)$ and a morphism $i: \text{Iso}(f, g) \rightarrow X$ such that $f \circ i \equiv g \circ i$, and such that for any object Z and morphism $z: Z \rightarrow X$ for which $f \circ z \equiv g \circ z$, there is a morphism $\bar{z}: Z \rightarrow \text{Iso}(f, g)$ for which $i\bar{z} \equiv z$; and if $z \equiv z'$, then $\bar{z} \equiv \bar{z}'$ for any such \bar{z} and \bar{z}' .

The notion of \mathcal{E} -cotensor is quite subtle. For an \mathcal{E} -cotensor, one relaxes the isomorphism in the definition of **Equiv**-cotensor to being an equivalence in **Equiv**. This is precisely analogous to the difference between **Equiv**-products and \mathcal{E} -products or between **Equiv**-inserters and \mathcal{E} -inserters.

Definition 24. An \mathcal{E} -cotensor of an equivalence relation X with an object A of an \mathcal{E} -category \mathbf{C} consists of an object A^X such that for every object

B , there is an equivalence $\mathbf{Equiv}(X, \mathbf{C}(B, A)) \simeq \mathbf{C}(B, A^X)$, natural in B , between the objects $\mathbf{Equiv}(X, \mathbf{C}(B, A))$ and $\mathbf{C}(B, A^X)$ of \mathbf{Equiv} .

These definitions are weaker than those of **Equiv**-products, **Equiv**-inserters and **Equiv**-cotensors. The **Equiv**-category **Setoid** has **Equiv**-products, **Equiv**-inserters, and **Equiv**-cotensors; so, *a fortiori*, it has \mathcal{E} -products, \mathcal{E} -inserters and \mathcal{E} -cotensors. However, the defining property of the latter only determines them up to equivalence within an \mathcal{E} -category. So any setoid that is equivalent to an **Equiv**-product in **Setoid** is itself an \mathcal{E} -product, although not necessarily an **Equiv**-product; similarly for inserters and cotensors.

The dual notions of \mathcal{E} -product, \mathcal{E} -inserter and \mathcal{E} -cotensor are called \mathcal{E} -coproduct, \mathcal{E} -coinserter and \mathcal{E} -tensor, following the bicategorical tradition. **Setoid** has **Equiv**-coproducts, hence \mathcal{E} -coproducts, but it seems not to have **Equiv**-coinserters or **Equiv**-tensors in general, but it does have \mathcal{E} -coinserters and \mathcal{E} -tensors.

Definition 25. An \mathcal{E} -category \mathbf{C} with finite \mathcal{E} -products is \mathcal{E} -closed if for every object X of \mathbf{C} , the \mathcal{E} -functor $(- \times X): \mathbf{C} \rightarrow \mathbf{C}$ has a right \mathcal{E} -adjoint.

Again, this is a weakening of the notion of **Equiv**-closedness. So, as **Setoid** is **Equiv**-closed, it is necessarily \mathcal{E} -closed. Just as for limits, \mathcal{E} -closed structure is only determined up to equivalence, so any setoid that is equivalent to an exponential $[A, B]$ is itself an \mathcal{E} -exponential, but might not be an **Equiv**-exponential.

7. The \mathcal{E} -category **Setoid**

Setoids and their morphisms form an \mathcal{E} -category **Setoid**, as already discussed in Example 16. In fact, **Setoid** is \mathcal{E} -equivalent to **Equiv**: the inclusion $J: \mathbf{Equiv} \rightarrow \mathbf{Setoid}$ is an equivalence on homs, and every setoid A is equivalent in the \mathcal{E} -category **Setoid** to $J(F(A))$, i.e., there are morphisms $r: A \rightarrow J(F(A))$ and $s: J(F(A)) \rightarrow A$ such that $s \circ r \equiv \text{id}_A$ and $r \circ s \equiv \text{id}_{J(F(A))}$.

We have already seen that **Setoid** has **Equiv**-products, **Equiv**-inserters, **Equiv**-cotensors, and **Equiv**-coproducts and is closed as an **Equiv**-category. So, *a fortiori*, it has all that structure as an \mathcal{E} -category too.

The only structure that we have not been able to address in the simpler context of **Setoid** as an **Equiv**-category, probably because it does not exist, is that of **Equiv**-coinserters and **Equiv**-tensors. **Setoid** does have \mathcal{E} -coinserters and \mathcal{E} -tensors, as we shall now describe.

Theorem 26. *The \mathcal{E} -category **Setoid** has \mathcal{E} -coinserters.*

Proof. Given morphisms of setoids $f, g: A \rightarrow B$, let $\text{Coins}(f, g)$ have carrier $|B|$, with $b_0 \approx_{\text{Coins}(f, g)} b_1$ determined by the transitive closure of the union of the sets given by \approx_B with, for each $a \in |A|$, a singleton set for each of $f(a) \approx g(a)$ and $g(a) \approx f(a)$.

This induces a setoid structure, with reflexivity axiom given by that for B , transitivity by construction, and symmetry by a combination of construction and that for B . Moreover, the inclusion inc generated by the identity morphism id_B has $\text{inc} \circ f \equiv \text{inc} \circ g$. The universal property holds by construction. \square

Theorem 27. *The \mathcal{E} -category **Setoid** has \mathcal{E} -tensors.*

Proof. Recall we defined J to be the inclusion of **Equiv** in **Setoid** (Proposition 11). Given an object X of **Equiv** and a setoid A , the product $J(X) \times A$ acts as an \mathcal{E} -tensor as

- for any setoid B , the object $\mathbf{Setoid}(J(X) \times A, B)$ of **Equiv** is isomorphic to $\mathbf{Setoid}(J(X), [A, B])$
- the setoid $[A, B]$ is equivalent (but not isomorphic) to $J(\mathbf{Setoid}(A, B))$, and
- for any object Y of **Equiv**, $\mathbf{Setoid}(J(X), J(Y))$ is equivalent to $\mathbf{Equiv}(X, Y)$.

\square

8. Conclusion

The idea of setoid came from the need for explicit provision of an equivalence relation on each set in constructive mathematics. But then we have the set of proofs of equivalence, and the next question is how to treat equivalence between proofs of equivalence. There are two extreme ways to do this: one is to take the degenerate equivalence relation and the other is to take the discrete one. The former leads to the category **Equiv**, and the latter leads to our category **Setoid**.

There is a further issue regarding equivalence: how to treat proofs of equivalence between functions. Enrichment of categories **Equiv** and **Setoid** over the Cartesian closed category **Equiv**, as we discuss in Sections 4 and

5, leads to degeneration of proofs. One could consider enrichment over the Cartesian closed category **Setoid** as well, but its correspondence with practice in theorem proving is not yet clear.

Enrichment over **Equiv** apparently is related to the notion of “proof irrelevance” discussed in connection with proof assistants, but the exact correspondence is left for further study.

Appendix A. Agda code for setoids and constructions on them

The following Agda code describes setoids and related constructions in the \mathcal{E} -category **Setoid**. Most of the code should be self-explanatory except for the names of the constructions. Those operators suggesting products, co-products and closures are really for \mathcal{E} -products, \mathcal{E} -coproducts and \mathcal{E} -closures. Moreover, `Eq` is for \mathcal{E} -inserters and `Coeq` is for \mathcal{E} -coinserters.
