Critical review of the literature

A comparison of the efficacy of psychological interventions for mania and depression in bipolar disorder: a systematic review.

According to DSM-V a diagnosis of bipolar disorder (BD) requires a history of major depression and either mania, hypomania or mixed episodes. Although there is substantial research in the field of psychological interventions for BD, including several reviews and meta-analyses, there is a lack of understanding about the differential effect of psychological intervention on depression and mania. This review sought to address this by synthesising available research of psychological interventions for BD and exploring the effects specifically on depression and mania. Systematic searches of databases were conducted and resulting studies were assessed for eligibility. In total 22 articles were included and these explored two broad psychological approaches; cognitive-behavioural therapy (CBT), which included a study of mindfulness-based cognitive therapy, and psychoeducation. One study also looked at other approaches and the effect of therapy on recovery from BD depression.

Results were reported for four key outcomes from studies that provided results separately for depression and mania; survival time to relapse, number of relapse episodes, symptom severity and time in episode. Findings from studies were highly inconsistent with some finding differential effects for depression and mania, some finding no benefit for either and others finding benefit for both. This prevented conclusions being drawn regarding the primary question of this review and instead highlighted the need for further consideration and consensus on what constitutes a meaningful outcome for individuals with BD. Furthermore, none of the interventions reported in the included studies appeared to be based upon a validated, disorder-specific theoretical model of BD. Clinical and research implications of these findings are discussed.
A trans-diagnostic cognitive behaviour therapy group in a secondary care mental health service.

This study investigated the effectiveness of a trans-diagnostic Cognitive-Behavioural Therapy (CBT) group delivered in a secondary care community mental health service. Using a published framework for service improvement the evidence base of trans-diagnostic interventions was explored and critiqued before the routinely collected outcome data of five group programmes was analysed. Pre- and post-group data, collected using the Clinical Outcomes in Routine Evaluation (CORE-10) and the Work and Social Adjustment Scale (WSAS), were available for 51 participants. Results of those who completed the group (n=42) showed that scores on both the CORE-10 and WSAS were significantly reduced over the duration of the group. These findings remained in an intention-to-treat sample (n=51).

The results suggested that the group had a positive effect on the symptoms and social functioning of those who attended. However, firm conclusions could not be drawn due to limited information collected about participant characteristics and effects of individual sessions. Recommendations, therefore, related to improving future evaluations of the group through the collection of more information. This included participant demographics and diagnosis, the use of additional disorder-specific outcome measures, pre- and post-group session-by-session feedback, a measure of CBT skill development and the collection of follow-up data.

The group was delivered following these recommendations and a further evaluation is reported that also comments on the implementation of these recommendations. Findings and suggestions for future research are discussed.
Main research project

A test of a cognitive model of violence: a comparison of thinking in violent and non-violent men.

The cognitive model of violence proposes that the beliefs and conditional assumptions of the individual, related to self-esteem, are important in the development of violent behaviour. It is suggested that this manifests as an enduring tendency to misinterpret ambiguous social situations as indicating that other people are critical of the person in ways signifying serious disrespect. This study tested the cognitive model of violence using a new measure, the Violence Interpretation Questionnaire (VIQ), which assesses interpretation and anticipated behavioural response to interpersonal and non-social situations. Three groups of men were compared; violent offenders (offender group; \(n=17\)) and two online control groups, one that reported violence (aggressive control group; \(n=28\)) and one that did not (non-aggressive control group; \(n=69\)). It was hypothesised that the violent participants would interpret VIQ interpersonal situations in a more negatively self-reverent manner than control participants, but that there would be no difference for non-social items. It was also predicted that VIQ interpersonal scores would correlate with another measure of violent thinking, the Maudsley Violence Questionnaire (MVQ).

Results showed that, in line with the primary hypothesis, the offender and aggressive control groups interpreted interpersonal situations more negatively than non-aggressive controls but no difference was found on non-social items. Interestingly, the VIQ aggression score of the aggressive control group was significantly lower than the offender group and no different to the non-aggressive controls. This suggests that although the aggressive controls interpreted situations like the offenders they anticipated responding like non-aggressive controls. VIQ interpersonal scores significantly correlated with MVQ machismo scores, providing some concurrent validity to the VIQ. These findings provide evidence for the role of negative, self-referent interpretations in the development of violence but also highlight a potential difference that comes into play after such an appraisal is made that differentiates the offenders from the aggressive controls.

Critical review of the literature

A comparison of the efficacy of psychological interventions for mania and depression in bipolar disorder: a systematic review.

Journal submission
This review will be submitted to the *Clinical Psychology Review*. This journal was chosen because it has a good five-year impact factor (9.86) and publishes high quality literature reviews specific to the field of clinical psychology (Appendix O).
Introduction

Bipolar disorder (BD) is estimated to affect around 1.5% of the population (Merikangas et al., 2007) and a diagnosis requires a history of both major depression and either mania, hypomania or mixed episodes (DSM-V; American Psychiatric Association, 2013). BD is associated with very high relapse rates with one study finding approximately 90% of patients relapse during the five years following initial onset (Tohen, Waternaux, & Tsuang, 1990).

The NICE guidance for the management of BD (CG185, 2014) suggests that patients with bipolar depression should be offered either a structured, manualised and evidence-based psychological intervention developed specifically for BD or a high-intensity therapy such as Cognitive-Behavioural Therapy (CBT) as outlined in the NICE guidance for depression. The guidance does not mention psychological intervention for the treatment of mania and hypomania, referring only to pharmacological treatments. Similarly, no mention of the psychological treatment of mania is made in the guidance for the longer-term management in secondary care, although general recommendations are made again for a structured, manualised, evidence-based psychological intervention with the aims of preventing relapse and reducing persistent symptoms that remain between episodes. These recommendations suggest that psychological interventions are effective for bipolar depression but by omission suggest that this is not so for mania, and pharmacology represents the only acute and prophylactic treatment for mania and hypomania.

When considering the current evidence base it seems that results across therapeutic approaches are inconsistent. Some reviews have concluded that psychological interventions are effective and that there is little difference in terms of benefit between them. For example, in their systematic review, Scott and Gutierrez (2004) found that adjunctive psychological therapy was beneficial for reducing relapse rates and results were comparable across different approaches including CBT, Family-Focused Therapy (FFT), Interpersonal Social Rhythm Therapy (IPSRT) and psychoeducation. Similar conclusions were made in a narrative review by Scott (2006), which found that, although psychological interventions reduced relapse rates, there was no evidence that one approach was more effective than another. This was further supported by a meta-analysis by Scott, Colom, and Vieta (2007) in which the authors also noted similarities between treatment approaches. However, other reviews have reported differences between therapies. For example, Beynon, Soares-Weiser, Woolacott, Duffy, and Geddes (2008) conducted a systematic review of interventions for the prevention of relapse and found that, in general, psychological interventions such as CBT and group psychoeducation were effective in reducing relapse, but psychosocial interventions, such as care management and integrated group therapy, did not demonstrate these benefits.

Several authors have noted the lack of knowledge about the mechanisms of action for different interventions (Geddes & Miklowitz, 2013; Lam, Burbeck, Wright, & Pilling, 2009; ...
Scott, 2006) and often psychological interventions appear to have been developed without a grounding in BD-specific theory (Jones, 2004). In addition, variability of outcome variables used in different studies further complicates interpretation of findings and potentially contributes to the inconsistent results reported within this field. For example, Beynon et al. (2008) focus on relapse prevention, whilst others, including Miklowitz (2008), also explore symptom severity and psychosocial functioning. Time-point of assessment is also an important consideration; although post-treatment outcomes provide useful information about the effectiveness of treatments, the effect that treatment has after it ends is arguably more important. This view appears to have been shared by Scott and Gutierrez (2004) who only included studies that reported a follow-up period of six months or more in their systematic review. Research studies that only include pre- and post-treatment data risk presenting misleading results as findings during treatment may well be confounded by other aspects of receiving a psychological intervention, for example having weekly meetings with a healthcare professional or the support of a group.

Despite the inconsistent findings in this area and the different recommendations provided by NICE for mania and depression in BD a review of the literature focusing on the differential effects of psychological interventions on depression and mania has not been conducted. However, initial reference to differential effects has been made in some reviews. For example, in their systematic review and meta-analysis, Scott and Gutierrez (2004) mentioned the efficacy of short interventions that address relapse prevention or medication adherence for symptoms of mania but not for depression, which they found requires longer, formulation-based interventions such as IPSRT and Cognitive Therapy (CT). Scott (2006) found that therapy appears to be more effective for symptoms of depression despite many interventions being developed to target and prevent manic relapse, such as FFT and IPSRT.

Miklowitz (2008) made some initial conclusions about treatment effects on depression and mania, although acknowledged that the number of studies detailing depression and mania independently were limited. It was suggested that interventions that target increasing medication adherence and early identification of prodromes are more effective for treating mania, whereas interventions that focus on the development of cognitive and behavioural skills for managing relationships are more effective in treating depression. However, with high variability of findings across outcome measures and studies it is unclear how these conclusions were derived. Furthermore, the review was not conducted using a systematic methodology, providing no safeguards against the omission of relevant studies and data, and potential bias in sampling. Little confidence can, therefore, be placed in these specific conclusions made in this review but it nonetheless adds to the argument for further research into whether or not psychological treatments for BD work equally well for symptoms of depression and mania.

Some efforts have been made to address the issue of treatment specificity in
psychopharmacology in a meta-analysis by Geddes, Burgess, Hawton, Jamison, and Goodwin (2004). They found a differential effect of lithium on mania and depression and this provided support for the use of this medication in individuals for whom symptoms of mania were the most debilitating problem. For psychological intervention of BD there is some preliminary evidence for differential effects on symptoms of depression and mania. However, the body of literature lacks a clear interpretation of such results that explores theoretical and clinical implications. The central objective of this exploratory review is, therefore, to provide a clear synthesis of research evidence relating to the psychological interventions for depression and mania in BD. This review seeks to ask a new question of the data presented in published randomised controlled trials (RCTs); are different psychological interventions for BD more effective for depression or for mania? Results will be considered with reference to psychological models of BD and the outcomes variables employed, and the clinical utility of findings will be discussed.

Method

Inclusion criteria

Design of studies

RCTs comparing a psychological intervention with a control condition were included in this review. Studies were written in English and included a quantitative statistical investigation of the effect of psychological intervention on the course or symptomatology of BD. Studies reported a follow-up period of at least three months after the end of the intervention (booster sessions were included in the period of intervention). Data were not reported elsewhere: in order to prevent duplication of findings in this review, where results were reported in an initial study and then again in a subsequent paper but with additional follow-up data, the former were excluded and the latter included.

Participants

Individuals were aged 18 years or over with a diagnosis of BD type I or II made according to DSM-IV, DSM-V or ICD-10 criteria\(^1\) using a standardised screening tool (i.e. Structured Clinical Interview for DSM-IV [SCID] or Mini International Neuropsychiatric Interview [MINI]).

\(^1\) DSM-IV introduced ‘hypomania’ and BD subtypes I and II. Studies using earlier versions were excluded on the basis that they might have excluded participants with less severe mania symptoms than more recent studies.
Exclusion criteria

A small number of studies explored the effect of specialist care that incorporated some type of psychological intervention with specialist pharmacology (i.e. Kessing et al., 2013). Such studies were excluded on the basis that it would not be possible to determine the effect of psychological intervention alone.

Selection of studies

Search information

The electronic databases PubMed, PsycNET, Scopus, Embase and the Cochrane Libraries were searched using terms grouped into three categories – ‘bipolar disorder’, ‘study design’ and ‘psychological therapy’ (see Appendix A). The search terms under these three headings were run using the Boolean operator OR and then run together using AND to ensure that resulting studies included a term from each of the three key categories. Additional searches were performed in Google Scholar as a further check to ensure no articles were missed. The databases provide different options so the searches in PubMed, Embase and Cochrane title and abstract searches were used whereas in PsycNET and Scopus searches of title, abstract and keywords were employed. Grey literature was not explored. Hand searching was conducted of relevant reviews in the field and the references of included studies were also checked.

Eligible studies

The initial searches produced 1332 results after duplicates were removed. The first author screened the titles and abstracts of these studies and a further review of full text was performed on the remaining 94 studies. (Reasons for exclusion of studies after full-text review are presented in Appendix B.) See Figure one for the study selection process.

The entire screening process was inter-rated by a trainee clinical psychologist. A sample (25%) of the 1332 identified studies was selected using a random sequence produced by the website, Random.org. Inter-rater agreement was 99.7% with a Cohen’s kappa coefficient of \( k=0.91 \). This was considered to be sufficiently high to justify the inter-rating of a proportion of the sample.

\[ \text{Landis and Koch (1977) provide guidance on measures of agreement of independent raters of categorical data. They suggested that a Cohen’s kappa coefficient of } 0.81-1.0 \text{ represented ‘almost perfect’ agreement.} \]

\[ \text{In total 333 articles were screened by second rater blind to the initial screen. On the basis of title and abstract 305 were excluded with 28 articles then reviewed in full. The second rater included six studies, five of which had been previously identified. After discussion this additional article was excluded.} \]

2 Landis and Koch (1977) provide guidance on measures of agreement of independent raters of categorical data. They suggested that a Cohen’s kappa coefficient of 0.81-1.0 represented ‘almost perfect’ agreement.

3 Landis and Koch (1977) provide guidance on measures of agreement of independent raters of categorical data. They suggested that a Cohen’s kappa coefficient of 0.81-1.0 represented ‘almost perfect’ agreement.
Data extraction

Data was extracted from studies and collated in a database. All data were checked for accuracy by a trainee clinical psychologist. Disagreements were discussed and the original article was consulted where appropriate to ensure all data reported were accurate.

Data items

Information extracted from each article comprised: inclusion criteria, location, sample size, age, gender, presentation at entry, diagnostic tool, symptom-related outcome measures, primary and secondary outcomes, details of intervention and control conditions, length of treatment and control, length of follow-up period and results.

Although there were a number of different outcome variables explored in the included studies, only those relevant to the research question of this review were identified; these were the variables for which it was possible to consider the results separately for depression and mania. For example, several studies reported symptom severity data for both depression and mania and these were included, whereas social functioning is a global measure of outcome in BD and was therefore omitted. Along with symptom severity at follow-up the outcomes identified were survival time to relapse, number of relapse episodes and time spent in episode. One study (Miklowitz et al., 2007b) focused on time to recovery for participants who fulfilled criteria for major depressive episode at intake; these results are discussed separately below.

Quality ratings

Included articles were rated for quality using a scale developed by Öst (2008). The Psychotherapy Outcome Methodology Rating Form (POMRF) comprises 22 items against which studies are rated (zero: poor, one: fair, two: good). The items relate to a range of aspects of the design of a study and once ratings have been made a total score is calculated (see Appendix C). This quality rating scale was selected due to it being designed for rating the quality of psychotherapy trials and it has been adopted in other reviews (i.e. Swain, Hancock, Hainsworth, and Bowman, 2013).
Figure one. Selection of studies

Results

A total of 2098 participants with BD were included in the 22 studies that met the inclusion criteria, details of which are presented in Table one. The studies explored the effect of three broad types of psychological intervention; CBT or CT (13 studies), psychoeducation (seven studies) and MBCT (one study). The remaining study differed in its design and explored the effect of CBT, IPSRT and FFT on time to remission from bipolar depression (Miklowitz et al., 2007b). Studies have been grouped together based on the main approach of the experimental intervention.

Study characteristics

CBT and CT intervention studies

Some studies investigated the effects of CBT interventions that were adapted specifically for BD. Ball et al. (2006) adapted CT for BD based upon their model of chronic
illness behaviour through the inclusion of psychoeducation, identification of warning signs and the importance of establishing stable routines. They compared this with treatment as usual (TAU) over a follow-up period of one year. Similarly, Meyer and Hautzinger (2012) compared adapted CBT with supportive therapy. Supportive therapy was said to differ from CBT in that the therapists adopted a ‘client-centred focus’ and dealt with any issues that the participant brought to the session, whereas the CBT treatment was based on individual formulation and linked the content to the individual’s experience. Jones et al. (2014) compared TAU with an adapted CBT intervention with the intention of reducing relapse and improving recovery in the first five years after onset. The authors list the main differences from standard CBT as being an emphasis on individual-focused goals rather than relapse prevention, a formulation-driven intervention as opposed to a standard model of bipolar experience, flexibility to work with what the individual brings to therapy, capacity to address comorbidities rather than focusing on depression and mania, and an emphasis on reducing self-critical and stigmatising language.

Weiss et al. (2007) compared an integrated group treatment for comorbid BD and substance dependence. Integrated group therapy consisted of 20 sessions of CBT-based relapse prevention that highlighted the similarities between BD and substance dependence. One of the key premises behind the intervention was that cognitions and behaviours that assisted in recovery from one disorder were likely to be beneficial to the other. This intervention was compared with 20 sessions of group drug counselling, a treatment that focused solely on recovery from substance dependence. Weiss et al. (2009) further developed this intervention with the aim of making it more ‘community-friendly’. The number of sessions was reduced from 20 to 12 and the experience required of therapists was reduced from doctoral to masters level with no expectation of formal CBT training.

Scott et al. (2006) delivered an individual CBT intervention based on Beck’s cognitive model of depression and the self-help guide by Scott (2002), which was informed by the stress-vulnerability model, and compared this to TAU. Gomes et al. (2011) developed a disorder-specific group CBT intervention also informed by this self-help guide. It covered four domains: psychoeducation, cognitive-behavioural strategies for managing depression and mania, skills for problems specific to BD including assertiveness and problem-solving, and relapse prevention. This intervention was compared to TAU over a follow-up period of one year.

The stress-vulnerability model informed several other studies that referred to the protocol of Lam, Jones, Hayward, and Bright (1999). This intervention combined medication adherence with psychological therapy, providing information on monitoring and managing prodromes, advocating regular sleep patterns and routines, and addressing extreme goal acquisition attitudes. Lam et al. (2000) compared this intervention with TAU and Lam, Hayward, Watkins, Wright, and Sham (2005) conducted a similar study with a longer follow-up period of two years.
González Isasi et al. (2010b) conducted a pilot study of the effect of a group intervention that combined CT, based on the protocol of Lam et al. (1999), with psychoeducation and compared this to monthly medication review. This intervention was further explored by González Isasi, Echeburúa, Limiñana, and González-Pinto (2014) in a subsequent study with a five-year follow-up period, and by Parikh et al. (2012) who compared 20 sessions of individual CBT with six sessions of the Life Goals Programme, a psychoeducational group intervention (Bauer & McBride, 2003).

Zaretsky, Lancee, Miller, Harris, and Parikh (2008) also compared CBT with psychoeducation. They delivered a seven-week psychoeducation intervention based on the manual of Basco and Rush (1996) and then those assigned to the treatment condition received a further 13 sessions of CBT, also based on this manual.

**Psychoeducation studies**

Similarly to the CBT group, some psychoeducational studies explored interventions developed specifically for BD. Castle et al. (2010) delivered a psychosocial group intervention based on the stress vulnerability model. This programme combined information and skills from four areas: monitoring mood and activities, assessment of prodromes, relapse prevention and goal setting. This intervention fell broadly under the umbrella of psychoeducation but also aimed to develop coping strategies. The control condition consisted of TAU but both groups also received weekly telephone calls. Smith et al. (2011) conducted an exploratory study of internet-based psychoeducation, ‘Beating Bipolar’, and compared to TAU. D'Souza, Piskulic, and Sundram (2010) developed a psychoeducation programme for participants with BD and a companion with the aim of improving the effect of interventions for the individual and those for caregivers alone. The Systematic Illness Management Skills Enhancement Programme-Bipolar Disorder (SIMSEP-BD) was compared to TAU (community-based case management with weekly 45-minute clinician review and monthly medication review).

Sajatovic et al. (2009) compared the manualised Life Goals Programme (Bauer & McBride, 2003) with TAU. Life Goals programme is based upon behavioural and self-regulation theories. Participants attend ‘phase one’, a six-week course of psychoeducational sessions, followed by an optional ‘phase two’, unstructured monthly sessions that focus on goal-setting and problem solving.

Colom et al. (2003b) explored group psychoeducation that they developed, similar to the Life Goals Programme. This was compared with a support group delivered by the same clinicians and at the same frequency as psychoeducation with a follow-up period of one-year. Psychoeducation aimed to increase illness awareness, compliance with treatment, identification of prodromes and relapse, and to establish regular routines. Colom et al. (2009b) employed this design but delivered an intervention published in their treatment manual (Colom & Vieta, 2006)
and reported a longer follow-up period of five years. Reinares et al. (2008) delivered this same intervention (Colom & Vieta, 2006) to caregivers; the participants with a diagnosis did not attend the group but outcomes were based on their symptoms and illness. This was compared to no intervention for caregivers.

**MBCT**

MBCT was adapted to include information about BD and this was compared with TAU (Perich, Manicavasagar, Mitchell, Ball, & Hadzi-Pavlovic, 2013).

**Systematic Treatment Enhancement Program for Bipolar Disorder (STEP-BD) study**

The study by Miklowitz et al. (2007b) focused on time to recovery from episode and participants were required to be in current major depressive episode at randomisation. The intervention condition was ‘intensive psychotherapy’ and this included three treatment arms: CBT, IPSRT and FFT. Intensive psychotherapy, with a maximum of 30 sessions over nine months, was compared with collaborative care; three individual 50-minute psychoeducational sessions held in the six weeks following randomisation.

**Outcomes**

Outcome data are shown in Table two and Appendix D. Results are presented using mean and standard deviations where available and significance was determined using $p<0.05$. The four primary outcomes (time to relapse, number of episodes, symptom severity and time in episode) are reported separately.

**Survival time to relapse**

Nine studies reported survival time to depressive and manic relapse. Six of these were CBT studies, four of which found no significant difference between CBT and control for survival time to depressive or manic relapse (Ball et al., 2006; Gomes et al., 2011; Meyer & Hautzinger, 2012; Parikh et al., 2012). However, two studies found significant differences to the control condition; Jones et al. (2014) found that recovery-focused CBT was associated with significantly longer time to both depressive and manic relapse than control and Lam et al. (2005) found significantly longer time to depressive relapse in the CT group, but no difference for manic relapse. Two psychoeducation studies reported this outcome; Castle et al. (2010) found that the intervention was associated with significantly longer survival time to depressive and manic relapse than the control condition, whereas Reinares et al. (2008) found that time to manic relapse was longer in the caregiver psychoeducation group compared to control, but no difference was found for depressive relapse. Perich et al. (2013), who explored MBCT, did not find any significant differences between intervention and control conditions.
The majority of CBT studies found no significant benefit of intervention over control for time to both depressive and manic relapse with only two of the six studies finding a significant result. Both psychoeducation studies reported some positive effects of treatment but with only two studies reporting this outcome it is difficult to generalise these findings. Furthermore, studies that reported significant differences compared treatment with control conditions of TAU (Castle et al., 2010; Jones et al., 2014), ‘minimal psychiatric care’ which appears similar to TAU (Lam et al., 2005) or no intervention (Reinares et al., 2008), whereas two of the five studies that did not find significant differences used an active control condition (Meyer & Hautzinger, 2012; Parikh et al., 2012). This makes it difficult to determine if positive effects from treatment arise from the psychological intervention itself or other aspects involved in receiving therapy.

**Number of episodes**

Twelve studies explored number of episodes; six CBT studies and five psychoeducation studies. Four CBT studies found no difference between CBT and control (Ball et al., 2006; Gomes et al., 2011; Lam et al., 2005; Scott et al., 2006) but two reported significantly fewer episodes in the intervention condition. Lam et al. (2000) found that there were significantly fewer hypomanic episodes in the CT condition compared with TAU, but no benefit of treatment over control for number of depressive or manic episodes after controlling for relevant baseline variables. Conversely, Weiss et al. (2009) found that the number of depressive episodes was reduced in the intervention condition, but not manic.

Castle et al. (2010) found significantly fewer depressive episodes in the psychoeducation condition but the number of manic episodes was less conclusive; none were reported in the treatment group compared to six in the control, whereas more hypomanic episodes were reported in the treatment group (nine versus five). Colom et al. (2003b) found fewer depressive and manic episodes in the treatment condition compared to controls, and these results were replicated in a subsequent study by Colom et al. (2009b). Reinares et al. (2008) found significantly fewer manic episodes but no significant difference between treatment and control for depressive relapse, and Smith et al. (2011) found no significant difference between groups for either depression or mania.

Again, many studies used TAU as the control condition with only one CBT study and two psychoeducational studies using an active control. Further difficulties in generalising these results arise when the definition of episode is explored, highlighting inconsistencies across studies. For example, some studies defined a bipolar episode through scores on symptom measures reaching a particular threshold (Colom et al., 2003b; Colom et al., 2009b), through applying DSM criteria (Ball et al., 2006; Castle et al., 2010; Gomes et al., 2011; Lam et al.,
2005; Scott et al., 2006; Smith et al., 2011) or by using a combination of measures, interviews and assessment tools (Lam et al., 2000; Reinares et al., 2008; Weiss et al., 2009).

**Symptom severity**

Twelve CBT studies, four psychoeducation studies and one MBCT study reported symptom severity scores for depression and mania.

Of the CBT studies two found beneficial effects of treatment compared to control for symptoms of both depression and mania. Lam et al. (2000) reported that once baseline ratings were controlled for the CT group showed significantly improved depression and mania symptoms and González Isasi et al. (2014) reported significant benefits of CT plus psychoeducation compared to the control condition for both mania and depression. Interestingly, these results were not found in the group’s earlier study that reported no significant difference between treatment and control groups (González Isasi et al., 2010b). The later study, however, included a five-year follow-up period which suggests that the benefits of this therapy increased over time (González Isasi et al., 2014). This assertion is further evidenced by the results over this follow-up period that show, with the exception of the final data point at five-years for mania ratings, the difference in symptom severity between control and intervention groups increased and at five-year follow-up the differences in mania and depression scores between the treatment and control groups were statistically significant.

Despite the positive findings of these two CBT studies, many others reported less promising results. Ball et al. (2006) found that blind clinician ratings of depression were significantly reduced at 12-month follow-up in the intervention group compared to controls, however, clinician-reported ratings of mania and all self-reported symptom measures of both depression and mania failed to identify any beneficial effect of CT compared to TAU. Lam et al. (2005) reported the opposite pattern of results with CT not associated with improved depression ratings compared to controls at any time-point, but mania scores were significantly reduced in the treatment group at 30-month follow-up.

The majority of the remaining CBT studies found no significant differences between CBT and control conditions for either depression and mania (Jones et al., 2014; Meyer & Hautzinger, 2012; Parikh et al., 2012; Scott et al., 2006; Weiss et al., 2009). Zaretsky et al. (2008) reported no significant difference between groups on depression ratings but did not report results for mania, despite administering a mania symptom measure (CARS-M). Finally, one CBT study reported higher depression and mania scores in the treatment condition compared to the control (Weiss et al., 2007).

Three of the four psychoeducation studies found no significant differences between intervention and control (Castle et al., 2010; Sajatovic et al., 2009; Smith et al., 2011) and the remaining study found significantly reduced mania ratings in the psychoeducation group
compared to TAU, but no benefit of treatment over control for symptoms of depression (D’Souza et al., 2010).

Perich et al. (2013) reported data for MBCT compared to TAU and found no significant difference on mania or depression scores.

In studies reporting symptom severity there was high variance on both the outcome measures used and the time-points at which data was collected. For example, some studies used self-reported symptom measures (González Isasi et al., 2010b), some used clinician-rated scales (Castle et al., 2010) and others used both (Ball et al., 2006). These inconsistencies make it difficult to satisfactorily compare results of different studies using means and standard deviations.

**Time in episode**

Five studies reported results for time spent in bipolar episode; three CBT studies and two psychoeducational. In CBT studies, Ball et al. (2006) found no significant difference from control, but two studies found that CBT was effective at reducing time in depressive episode. Lam et al. (2005) reported that participants in the CT group spent significantly fewer days in depressive episode than controls over the 30-month study period after controlling for number of previous episodes and medication adherence, but that no significant difference was found for mania. Similarly, Zaretsky et al. (2008) found that participants in the CBT group had significantly fewer days in depressive episode than the control group. No data or results were reported on time spent in mania despite using the National Institute of Mental Health Life Chart Method (Denicoff et al., 2000), which collects daily ratings of both depression and mania.

Similarly, the psychoeducation study by Castle et al. (2010) did not report results for time spent in manic episode, only presenting data for depression showing that the treatment group spent significantly less time in depressive episodes than controls. Colom et al. (2009b), however, reported significantly less time in both depressive and manic episode in the treatment group compared to the control.

As with the other outcomes reported here there is variance between studies on the definition of this variable. For example, some studies defined an episode by self-reported symptoms (Ball et al., 2006; Zaretsky et al., 2008) whilst others measured time in which the participant fulfilled DSM criteria (Castle et al., 2010; Colom et al., 2009b), and one paper did not provide a definition (Lam et al., 2005).

**STEP-BD study**

The design and outcomes of the STEP-BD study (Miklowitz et al., 2007b) is different to all other included studies and, as such, the results are not reported in Table two. The study reported the effect of treatment on time to recovery from depressive episode. The results showed that participants in the intensive psychotherapy condition were more likely to recover
than those who received collaborative care (one-year recovery rate: intensive psychotherapy group, 105/163 [64.4%]; collaborative care group, 67/130 [51.5%]; \( p=0.01 \)). When type of intensive psychotherapy was considered there was a main effect of treatment type (\( p=0.046 \)) but when pairwise comparisons of the three treatment types were conducted using an intention-to-treat sample, no significant differences were found. Miklowitz et al. (2007b) suggested that this may have been due to the study being underpowered or to the commonalities of psychological interventions. Results for the proportion of the sample classified as well across the 12-month duration of the study showed that participants in the intensive psychotherapy condition were more likely to be well at any time-point than those in the collaborative care group (\( p=0.003 \)).

The differences in baseline participant characteristics and outcome variables and the lack of results for mania make these results difficult to compare with other studies.

**Quality ratings**

The methodological quality of included studies was rated using the POMRF system. This was previously employed by Swain et al. (2013) who defined quality categories in relation to distance from the overall mean score of studies in their review. Using this approach the overall mean POMRF score in the current review was calculated as 21.59 (\( SD=3.86 \)) and scores ranged from 14 to 28. Scores within one standard deviation of this mean were rated as ‘below average’ (17.73-21.58) or ‘above average’ (21.60-25.45) and those more than one standard deviation from the mean were rated as ‘well below average’ (0-17.72) or ‘well above average’ (25.46 and above). POMRF total ratings are presented in Table one and raw scores are reported in Appendix C.

The ratings of quality of included studies highlighted some important methodological flaws. For example, 15 of the 22 included studies reported no power calculation, 15 did not provide details of the training provided for assessors of outcome variables and in all but three studies the number of therapy hours in the control and treatment conditions differed ‘markedly’ according to the rating system. When studies investigating CBT and psychoeducation were grouped together and mean quality scores were calculated the results showed both groups were in the below average range with 20.62 and 19.71 respectively. The one MBCT study was in the above average range and the STEP-BD study fell in the below average range. Quality was also reviewed for the studies reporting data for different outcomes to investigate the generalizability and reliability of the results.

Note: Dep=depression, Man=mania, * indicates a significant positive effect of intervention compared to control, - indicates no difference between intervention and control, X represents a significant negative effect of intervention compared to control. Cells with a dark grey background indicate differential effects of intervention on depression and mania within studies. Cells with a light grey background indicate missing data.
Discussion

This review sought to consider the effects of different psychological interventions for BD on depression and mania as reported in studies with a follow-up period. Previous reviews have found some evidence to suggest that different interventions have differential effects on depression and mania (Scott & Gutierrez, 2004) but a comprehensive review of the literature with this focus was lacking.

Table two highlights the difficulties in addressing the central question of this review including the inconsistency of results, both within and between treatment approaches and outcomes, and the disparity between studies regarding the outcome variables reported. These issues prevent definitive conclusions from being drawn and raise questions about the basis of the preliminary conclusions related to the effects of therapy on depression and mania made by Miklowitz (2008).

Studies that were predominately CBT-based were considered together and the results showed that, although there were some positive findings, the majority of studies found no significant difference between CBT and a control condition for a range of outcomes and for both depression and mania. Furthermore, there are caveats to some of the positive findings presented in Table two. For example, Ball et al. (2006) reported that depressive symptoms were significantly improved in the CT group. However, this was based on one outcome measure whereas no significant difference was found between groups on three other measures of depression. Lam et al. (2000) reported a positive effect of CT on the number of hypomanic episodes, but this did not apply to episodes of mania after controlling for baseline variables. The findings suggest that CBT is not associated with consistent and convincing benefits for individuals with BD when considering the effect on outcomes relating to depression and mania.

There were fewer studies that investigated psychoeducational interventions for BD and, as with the studies of CBT, results were inconsistent across outcomes and symptoms. Almost all of the studies that reported symptom severity as an outcome found no difference between psychoeducation and control condition for both depression and mania - with just one study (D'Souza et al., 2010) finding a positive benefit over control condition for ratings of mania. However, more convincing were the results relating to number of bipolar episodes. Psychoeducation was associated with fewer episodes of depression and mania compared to control conditions in the majority of studies. These results may be a reflection of the effect of psychoeducation that teaches participants about relapse and aids its prevention, but may not be effective in reducing the experience of the symptoms of depression and mania.

MBCT was investigated in one study (Perich et al., 2013) and the results do not support the use of MBCT in the treatment of depression and mania in BD.
The STEP-BD study (Miklowitz et al., 2007b) was not easily incorporated into this review due to its different focus and choice of outcome variables. However, the results are interesting as they show that intensive psychotherapy was beneficial for participants recovering from a major depressive episode irrelevant of the type of therapy received (CBT, IPSRT, FFT). However, the control condition included only three sessions of psychoeducation; a control intervention of equal length and intensity to those delivered in the treatment condition would have allowed for more meaningful comparison. (This was also a limitation of other included studies.)

This review highlights the inconsistent results of studies in this area and allows for consideration of some other interesting findings. The lack of theoretical models of BD identified in previous reviews, together with inconsistencies in the results of studies included in the current review, led to closer examination of the conceptual underpinnings of the interventions delivered. Although many studies used published protocols and manuals, it appears that none of the interventions were based upon a validated, disorder-specific model of BD. Furthermore, there seems to be significant overlap between different interventions; with the exception of the ‘Barcelona Bipolar Disorder Programme’ used in some studies (Colom et al., 2009b; D'Souza et al., 2010; Reinares et al., 2008), the psychoeducational interventions all provided elements of CBT, and the CBT interventions included some aspects of psychoeducation. Perhaps this is unsurprising given the reliance on theories borrowed from generic mental health and chronic physical ill health. Considering the inconsistent results of these interventions across a range of outcomes, which were often no different to control conditions, and the profoundly disruptive effect of BD upon individuals with this diagnosis, it seems important that future research into the treatment of BD has disorder-specific theoretical underpinnings.

One such disorder-specific conceptual model is the integrative cognitive model (Mansell, Morrison, Reid, Lowens, & Tai, 2007). This theoretical framework places central importance on the interpretations made by the individual on changes in internal states. It suggests that the nature of such interpretations will determine the behaviours and strategies that the individual uses in an attempt to exert control over their internal state and to self-regulate. However, these strategies and behaviours can form part of a vicious cycle of altered internal state, misinterpretation, strategies to attempt to self-regulate or exert control and further changes to internal state.

This model has been validated in studies that have seen a distinction in the types of appraisals and beliefs held in regards to changes in internal state between groups of participants with BD, unipolar depression and non-clinical controls (Mansell & Jones, 2006; Mansell et al., 2011). Based upon this model a CBT intervention was developed and described by Mansell (2007). This therapy seeks to help the individual with BD to develop insight into the extreme personal appraisals of changes in internal state and to find strategies to counter ascent and
descent behaviours. A case series using this therapy (Think Effectively About Mood Swings; TEAMS) was conducted and found promising initial results with some indication that the intervention had a greater effect on symptoms of depression (Searson, Mansell, Lowens, & Tai, 2012). The small sample size and lack of a control condition prevented strong conclusions being made but this study has been followed by the publication of a trial protocol for a larger RCT of the TEAMS intervention (Mansell et al., 2014). The group have considered appropriate outcome variables and, rather than focusing only on preventing relapse, which they argue has been found to be just one part of a patient’s view of recovery, they will focus on the things described by the individual as maintaining their difficulties. As such the study will assess the severity of mania and depression, anxiety, thinking styles and social functioning.

This review also highlights the diversity of outcome variables explored in studies in this field, and the lack of consensus on what constitutes a successful outcome for individuals with BD. For example, should interventions be striving to ‘cure’ a patient of BD, with no subsequent relapse or symptoms of depression or mania? Or instead are there variables that would increase quality of life for those with BD, for example, reducing length of time in episode and the severity of depression and mania when relapse occurs? There are several other outcomes that have not been reported in this review including social functioning, quality of life, medication adherence and days spent in hospital, each with its own complexities and confusions around what represents a positive result. For example, some studies reported medication adherence and considered consistent blood plasma levels to be a positive outcome. However, the reasons for this are unclear; stable plasma levels may indicate increased insight into BD but could also represent increased motivation due to deterioration in symptoms, and conversely, poor adherence could indicate an individual feeling more able to manage their symptoms without pharmacology. The wide range of outcomes explored in different studies leads to difficulties in drawing conclusions about the effectiveness of different interventions both within and between studies.

Limitations

The main psychological therapies explored in the published literature are CBT, psychoeducation, IPSRT and FFT. Unfortunately, with the exception of the STEP-BD study (Miklowitz et al., 2007b), the studies included in this review only investigated CBT and psychoeducation. The majority of studies exploring IPSRT and FFT were excluded due to the use of diagnostic criteria other than DSM-IV or ICD-10 and/or the lack of a follow-up period. Although the robust criteria for included studies is a strength it has resulted in a narrower range of interventions being compared and, as such, conclusions about the effectiveness of other interventions cannot be made.
The outcome variables in this review were selected because it was possible for studies to report results separately for depression and mania. However, this has resulted in several other important outcomes being omitted (i.e. social functioning) and this may have led to an inaccurate view of the effectiveness of different interventions overall.

A further difficulty arises when baseline participant characteristics are considered with some studies recruiting those currently in episode, others requiring individuals to have been euthymic for a period of time prior to the study and others making efforts to gain a representative sample through minimal exclusion criteria. These differences further complicate the interpretation of results.

Finally, the overall quality of studies included in this review was variable and the quality rating process highlighted some significant methodological flaws, raising further doubts about the generalizability and reliability of results of studies in this field.

**Clinical implications**

This review highlights some of the complicating factors for clinicians and patients in identifying the most appropriate intervention for BD. Unfortunately it has not been possible to provide definitive conclusions regarding the most effective intervention for depression and mania. The inconsistencies in results despite many studies employing similar interventions adds to the rationale for further research about the phenomenology of BD and may support the theory that, contrary to popular conceptualisations of bipolar depression and mania being opposite ends of a spectrum, depression and mania are dissociable processes (Johnson et al., 2011; Pavlickova et al., 2013). This theory may explain why treatment for unipolar depression (i.e. CBT) or psychoeducation does not appear to be consistently effective. According to the integrative cognitive model (Mansell et al., 2007) bipolar depression may be at least partly influenced by the individual’s avoidance of mania; in trying to avoid the potentially devastating effects of a manic episode individuals may become hypervigilant for signs of hypomania and take efforts to avoid ascent in mood, such as social withdrawal, that could conceivably contribute to low mood. Treatments of unipolar depression, therefore, may not have a good effect unless the underlying negative appraisals about mania are addressed; something that does not appear to be included in the intervention protocols reported here. Furthermore, psychoeducation emphasises the importance of recognising manic prodromes and the development of skills to avoid mania, an intervention that could arguably reinforce the individual’s negative beliefs and appraisals about mania. Similarly, negative appraisals about depression could lead the individual to employ strategies that might contribute to symptoms of mania, and psychological interventions that focus on avoiding low mood could serve to reinforce negative appraisals of depressive prodromes.
Future research directions

There are several obvious areas for future research, primarily the development of interventions based upon validated disorder-specific theoretical models. More recent and current studies of widely used interventions, such as IPSRT and FFT, should be conducted as the outdated diagnostic screens employed in many studies prevented their inclusion in this review. Consideration and research should be focused on determining the most appropriate outcome variables and this should be centred on those things identified by individuals with BD as being meaningful goals of treatment.

Conclusions

Over a decade ago Jones (2004) reviewed the evidence for psychotherapy of BD and outlined some important considerations for future research into effective treatments. These included the need for standardised outcome measurement, for treatment approaches to be based upon theoretical models and for the differential effects of treatment on depression and mania to be further explored. Although some studies and reviews have made some progress in addressing these issues it seems that these recommendations are as pertinent now as they were in 2004.

Service improvement project

A trans-diagnostic cognitive behaviour therapy group in a secondary care mental health service.

Journal submission
This review will be submitted to the Cognitive Behaviour Therapist. This journal was selected because it publishes articles detailing examples of clinical practice for disseminate to clinicians and this project seemed particularly relevant for this audience (Appendix P).
Introduction

This service improvement project aimed to evaluate the effectiveness of a trans-diagnostic CBT group held within a secondary care mental health service by analysing data available for the group and comparing the results to the published literature in this field. A model of improvement was used as a framework for the project as shown in Figure one (Langley et al., 2009). This model details stages for improving an aspect of a service, including the development of clear goals, considering how positive outcomes can be demonstrated and identifying the most appropriate changes that can be made. These stages then lead into more specific change processes based on the Plan-Do-Study-Act (PDSA) cycle. A plan is developed in order to meet the specific objectives of the project and consideration is given to what data that is necessary to illustrate change. This plan is then employed and the results are analysed and evaluated, informing the development of subsequent PDSA cycles.

What are we trying to accomplish?

How will we know if a change is an improvement?

What changes can we make that will result in improvement?

Act  Plan

Study  Do

Figure one. Model for improvement including the PDSA cycle.

The decision to use this model of improvement was made to ensure that the original questions asked by the service were answered in a systematic manner. The first part of the project comprises of an evaluation of the group, informed by literature in this field, and some recommendations for changes to improve the effectiveness of the group. The second part of the project forms a PDSA cycle in which the findings of the evaluation and the recommendations were implemented.
Part one: model for improvement

What were we trying to accomplish?
A secondary care mental health service wanted to know whether or not the trans-diagnostic CBT group that they deliver is an effective treatment. They also wanted to improve the outcomes for the service users attending.

How would we know that a change was an improvement?
The literature on trans-diagnostic CBT groups was reviewed and the results from the group in question were compared to those in the published research.

What changes were made?
Based upon the literature review and the evaluation of the group, recommendations were made with the aim of improving the effectiveness of the group.

The state of the evidence: a literature review

Cognitive Behaviour Therapy (CBT) is the first line treatment for a range of different psychological problems including depression (NICE, 2009), generalised anxiety disorder, panic and agoraphobia (NICE, 2011), schizophrenia (NICE, 2013) and eating disorders (NICE, 2004). There is growing evidence that this is, in part, due to common processes across disorders (Mansell et al., 2008). Mansell et al. (2008) outline the advantages of a trans-diagnostic approach, stating that it can help to explain co-morbidity of problems; it can allow theories and understanding of particular problems to be generalised to others, and it can potentially inform trans-diagnostic interventions.

There are several practical applications to trans-diagnostic interventions. Interventions that are less disorder-specific and instead focus on common processes would allow treatment to be offered in a group format to a large number of people reducing both costs and waiting times. Rather than either receiving individual psychological intervention or waiting for sufficient numbers with similar problems to justify a group intervention, trans-diagnostic group interventions would allow therapists to treat greater numbers and sooner. It is also possible that overall treatment duration would be reduced because, unlike traditional interventions that typically target the primary diagnosis before moving on to remaining difficulties, the trans-diagnostic approach would employ a more global focus. However, this hypothesis requires further investigation.

There is now a substantial body of literature exploring the utility of the trans-diagnostic approach. However, the majority of this research refers to trans-diagnostic anxiety interventions.
and excludes non-anxiety diagnoses. Norton and Hope (2005) reported one of the first such studies in which 19 participants with anxiety disorders were randomly assigned to either a trans-diagnostic CBT group or wait-list control. Those who received the CBT intervention showed significantly greater improvement in symptom severity and on idiographic fear and avoidance hierarchies. However, no significant differences were observed on self-reported anxiety symptoms.

Following this initial study Norton (2008) explored the effect of diagnosis on outcome using a sample of 52 participants with anxiety disorders. Although the author acknowledges that the study may be underpowered, the results showed no differential effect of diagnosis on treatment outcome with significant decreases in anxiety scores across disorders and a large effect size ($d=1.06$). Interestingly, those with higher severity scores at pre-treatment showed the biggest improvement, suggesting that an upper cut-off for severity in the inclusion criteria for such groups may not be necessary.

Erickson et al. (2007) randomised a larger sample ($n=152$) with anxiety disorders to either a trans-diagnostic CBT group or a wait-list control. Unlike Norton and colleagues, who focused on common processes across anxiety disorders, Erickson et al. (2007) also addressed some disorder-specific features. The results showed a significant decrease in anxiety scores with a medium effect size ($d=0.5$). Although the effect was substantial, it was smaller than that expected of disorder-specific treatments and those found in subsequent studies of trans-diagnostic group CBT (Norton, 2008). The authors suggest that perhaps too much information was presented and too many skills were discussed and refer to the treatment protocol outlined by Norton and Hope (2008) as being a more selective approach in terms of skills presented that nonetheless obtained good results.

More recently research has been conducted using an alternative intervention for the control condition instead of a waiting-list sample. Norton (2012) compared trans-diagnostic CBT group intervention with relaxation training. The efficacy of the two groups was broadly equal but the attrition rate for the CBT group was significantly lower than that of the relaxation group. Furthermore, the results showed that the efficacy of the trans-diagnostic CBT group was comparable to that of disorder-specific protocols ($d=1.43$). No differential effect of diagnosis on treatment outcome was found, further supporting the use of a trans-diagnostic approach. Norton and Barrera (2012) randomised participants with panic disorder, social anxiety disorder or generalised anxiety disorder to either trans-diagnostic CBT group intervention or disorder-specific group treatment. They concluded that there were no significant differences in terms of efficacy of the two interventions and highlighted the substantially reduced waiting times for the trans-diagnostic treatment.

Research has also investigated the effect of trans-diagnostic CBT groups on comorbid diagnoses. Data reported by Norton and Hope (2005) was analysed further to investigate the
effect of the treatment on secondary symptoms of depression (Norton et al., 2004). The results showed that participants in the treatment condition showed a significantly greater reduction in depressive symptoms compared to the wait-list control. These findings were supported by those of Mohammadi, Birashk and Gharaie (2013) who demonstrated significant reductions in anxiety and depression over the duration of a trans-diagnostic CBT group, albeit with a non-clinical sample of undergraduate students with symptoms of anxiety and depression. More convincingly, Norton et al. (2013) analysed data from three earlier studies to investigate the effect of the trans-diagnostic treatment protocol on comorbid symptoms; predominantly secondary anxiety disorders and affective disorders. They found that around two thirds of participants with at least one comorbid diagnosis did not meet the criteria for a clinically severe secondary diagnosis at the end of treatment and this effect was not dependent on secondary diagnosis type. Furthermore, the authors found that this effect was larger than that found in disorder-specific CBT treatments for anxiety, although no effect sizes were reported.

Larsen-Barr and Glynn Owens (2013) conducted a similar study but included comorbid psychosis in their sample. The group provided support and psycho-education and was based upon the theory that negative affectivity, which is defined as the tendency to experience emotions more quickly and more intensely, may be present across disorders. Despite a very small sample size (n=9) and no statistically significant conclusions being drawn, the authors suggest that the group was beneficial to individuals irrelevant of diagnosis including those with a schizophrenia spectrum disorder.

Despite the extension of research to comorbid problems there is a scarcity of studies directly assessing the efficacy of trans-diagnostic groups for other diagnoses. However, it seems that this is an emerging area of research. Kristjánsdóttir et al. (In review) investigated the efficacy of a trans-diagnostic CBT group in Iceland for patients with depressive and/or anxiety disorders and used specific as well as generic outcome measures to explore differential effects according to diagnosis. They found comparable results on specific outcome measures to those found in IAPT services in England and concluded that although the study may be limited due to power considerations, these preliminary findings support the case for extending the inclusion criteria for trans-diagnostic groups from solely anxiety diagnoses.

In their meta-analysis of trans-diagnostic group interventions for anxiety disorders Norton and Philipp (2008) found the large effect sizes for pre- to post-treatment improvement (d=1.29) to be comparable with studies of disorder-specific protocols (d=1.58). (Although the authors advised cautious interpretation of the results as the evidence for disorder-specific treatment is, to date, more rigorously controlled than that of trans-diagnostic intervention.) Since this review was published some studies have begun to explore the use of trans-diagnostic group intervention for non-anxiety diagnoses. However, there is currently only a clear evidence-based grounding for such intervention in the treatment of anxiety disorders.
Evaluation of the trans-diagnostic CBT group

Method

Participants

Participants were adults under the care of a secondary care mental health team and as such were experiencing significant mental health difficulties requiring multi-disciplinary professional support. Participants were referred to the group by a clinician in the team and were then assessed by a group facilitator. Inclusion criteria were that the group facilitator judged that the individual was motivated to engage and able to commit to regular attendance.

A total of 56 participants started the group between 2010 and 2013 in five cohorts and data were routinely collected by the group facilitators. Participant characteristics are displayed in Table one. Data were missing for five participants who were therefore excluded from analysis. In total there were sufficient data for analysis of 51 participants, 31 of whom were female. No data on age or ethnicity were collected. Participants were categorised into diagnosis type based on their primary diagnosis which was obtained from the referral form, patient notes or during the assessment. The first diagnosis listed in the results database was considered the primary diagnosis. Diagnoses were divided into three categories; anxiety disorder, depressive disorder or psychotic disorder (including bipolar disorder) and represented 5.9%, 64.7% and 29.4% of the sample respectively. Comorbidities were recorded in 19.6% of participants.

Measures

The following outcome measures were administered at pre-group individual sessions and during session 12.

Clinical Outcomes in Routine Evaluation-10 (CORE-10; Evans et al., 2000)

The CORE-10 is a short self-report measure of general subjective clinical outcome including wellbeing, symptoms, general functioning and risk to self or others. The CORE-10 has been shown to be a valid and reliable measure that is sensitive to change (Evans et al., 2000) and can be used across different settings and professions (Evans et al., 2002) and disorders (Barkham et al., 2013).

Work and Social Adjustment Scale (WSAS; Mundt et al., 2002).

The WSAS is a five-item self-report measure of functional impairment that has been demonstrated as a reliable and valid tool for research. It has been validated with various
disorders including depression, OCD (Mundt et al., 2002) and phobic disorders (Mataix-Cols et al., 2005).

Procedure

A CBT-therapist and a clinical psychologist designed the group structure and content. Treatment consisted of 12-weekly one and a half hour sessions with a booster session delivered four weeks after session 12. Each participant was also offered three one-hour individual sessions. The group and individual sessions were facilitated by clinical psychologists, nurses, social workers and occupational therapists with supervision provided by a clinical psychologist on a monthly basis. The group format and session content are displayed in Appendix E.
The first individual session was held before the start of the group and provided participants with information about the group and individual requirements such as homework. Pre-group outcome measures were completed at this point. Two further individual sessions were held between sessions three and four and six and nine, and offered support in developing and applying the skills introduced in the group, as well as problem-solving any difficulties that arose.

Results

Attrition

Nine participants (17.6%) did not complete the group programme. Rates of attribution did not differ for gender (Fisher’s exact test yields \( p=0.223 \) indicating no difference) or primary diagnosis type \( (\chi^2(2)=0.71, n=51, p=0.702) \).

Further analysis of pre-group outcome measure scores indicated no significant differences between those who completed the group (CORE-10; \( M=22.45, SD=8.45, WSAS; M=24.60, SD=7.51 \)) and those who did not (CORE-10; \( M=24.89, SD=8.43, WSAS; M=27.44, SD=6.98 \)); CORE-10; \( t_{40}=0.79, p=0.436, WSAS; t_{40}=1.05, p=0.301 \). This was also reflected in the descriptive statistics of clinical cut-offs on both the CORE-10 and WSAS\(^1\). 100% of participants who did not complete the group met the clinical cut-off for both the CORE-10 and WSAS whilst of participants who completed the group the clinical cut-off was met by 92.5% for the CORE-10 and 100% for the WSAS.

Treatment efficacy

The pre- and post-group scores for outcomes measures are shown in Figure two. A paired samples \( t \)-test was conducted on CORE-10 scores of completers \( (n=42) \) at pre-group \( (M=22.45, 95\% \ CI=19.9-25.0, SD=8.45) \) and post-group \( (M=14.92, 95\% \ CI=13.51-16.33, SD=7.68) \) and found a significant decrease at the end of the group \( (M=7.52, 95\% \ CI=4.5-10.54, SD=9.96); t_{41}=4.9, p<0.001 \). This represents a large effect size (Cohen’s \( d=0.93 \)), indicating that over the course of the group distress experienced by participants significantly improved.

A significant decrease \( (M=8.0, 95\% \ CI=5.9-10.1, SD=6.92) \) was also found between WSAS scores at pre-group \( (M=24.6, 95\% \ CI=22.33-26.87, SD=7.51) \) and post-group \( (M=16.6, 95\% \ CI=14.37-18.83, SD=7.4); t_{41}=7.49, p<0.001, \) with a large effect size (Cohen’s \( d=1.07 \)). This indicates that the social functioning of participants was significantly improved at the end of the group.

\(^1\) Clinical cut-off for the CORE-10 and WSAS was a score of 10 or more.
Figure two. Mean pre- and post-group outcome measure scores.

Figure three. Mean pre- and post-group outcome measures including pre-group scores carried forward for intention to treat analysis.

An intention to treat analysis was also conducted with pre-group scores carried forward for participants who did not complete included (n=51). Results are displayed in Figure three. A paired-samples $t$-test found the significant decrease in CORE-10 scores remained with the inclusion of these participants (pre-group; $M=22.88$, 95% CI=20.53-25.23, $SD=8.42$, post-group; $M=16.69$, 95% CI=14.32-19.06, $SD=8.63$, difference; $M=6.20$, 95% CI=3.59-8.81, $SD=9.47$); $t_{[50]}=4.68$, $p<0.001$, $d=0.73$, as well as for WSAS scores (pre-group; $M=25.10$, 95% CI=23.06-27.14, $SD=7.43$, post-group; $M=18.51$, 95% CI=16.22-20.8, $SD=8.37$, difference; $M=6.59$, 95% CI=4.67-8.51, $SD=6.99$); $t_{[50]}=6.74$, $p<0.001$, $d=0.83$. 

52
One-way between-subjects ANOVAs were conducted to investigate the effect of diagnosis on pre-group CORE-10 and WSAS scores of completers. At the \( p<0.05 \) level there was not a significant effect of diagnosis on pre-group CORE-10 scores (\( F_{[2,39]}=1.36, p=0.270 \)) or WSAS scores (\( F_{[2,39]}=0.21, p=0.814 \)), indicating that the diagnostic category of participants did not affect severity of symptoms or level of functioning at baseline.

Further one-way between-subjects ANOVAs were conducted to compare the effect of primary diagnosis on post-group CORE-10 and WSAS scores. These tests showed no significant effect of primary diagnosis on post-group CORE-10 scores (\( F_{[2,39]}=0.49, p=0.619 \)) or WSAS scores (\( F_{[2,39]}=0.19, p=0.827 \)) indicating that participants benefitted from the intervention irrespective of primary diagnosis.

Due to the small sample size and uneven distribution of participants attending different number of sessions it was not possible to statistically analyse the effect of number of sessions on outcomes variables. However, Table two displays the mean difference in CORE-10 and WSAS scores for participants attending different numbers of sessions. The most substantial improvement on CORE-10 and WSAS scores appears to be in those who attended eight sessions, but there are insufficient numbers for conclusions about optimum levels of attendance to be drawn.

**Booster session**

Of the 42 participants who completed the group 50% attended the booster session. Post-group outcome measure data was obtained at session 12 and as such cannot provide an indication of the utility of the booster session. Differences between the groups were explored through an independent samples t-test of the post-group CORE-10 scores of those who attended the booster (\( M=13.41, SD=8.02 \)) and those who did not (\( M=16.71, SD=7.07 \)) and found no significant difference between the two; \( t_{[40]}=1.53, p=0.134 \). Non-significant differences were
also found between post-group WSAS scores of those who attended the booster session \((M=15.33, p=7.7)\) and those who did not \((M=17.86, p=7.04); t(40)=1.11, p=0.274\).

**What do these results show?**

Trans-diagnostic group CBT interventions for mental health problems are gaining evidence to support their effectiveness with positive outcomes demonstrated in a range of diagnoses with a particular focus on anxiety disorders. This is the first study investigating the efficacy of a trans-diagnostic CBT group that does not exclude participants on the basis of diagnosis. In contrast to the published literature the group programme in the current study is open to participants with any mental health diagnosis under the care of a secondary care mental health service. The data from five cohorts show that the group is associated with significant improvements in subjective distress and functioning, irrespective of diagnosis type. Although the effect sizes of the mean decrease in symptom severity and functional impairment are smaller than those reported in a meta-analysis by Norton and Philipp (2008), they still indicate large effects.

The study was conducted in routine clinical practice and as such provides an ecologically valid account of the effect of this intervention. However, there are a number of limitations that should be considered. Limited data on diagnosis has prevented detailed analysis of the effect of the group on specific diagnoses. Although the group has been demonstrated to be effective across the broad diagnostic categories reported, it is not possible to conclude whether the group is particularly beneficial to any specific diagnoses. Additionally, limited demographic information for the participants was collected and it is therefore not possible to explore the potential confounding effect of variables such as age, employment status, adjunctive medication, and previous or current additional psychological therapy. The relatively small sample size also limits the validity of between-group analyses of diagnostic categories.

Although the pre- and post-group outcome measures provide information on the effect of the group as a whole, no session-by-session outcome data was collected. This prevented an analysis of the change associated with individual sessions and the identification of specific trans-diagnostic processes that the group targets. It is therefore not possible to determine the components of the group that affected the positive changes observed but we can hypothesise about the factors that may have been involved.

The positive findings of the group may also be less generally trans-diagnostic and instead may be attributed to symptoms and trans-diagnostic processes of anxiety. For example it cannot be ruled out that the group predominantly improves anxiety, in line with the research evidence, and that those with other diagnoses, such as depression, bipolar or psychosis also have comorbid anxiety. This seems plausible given that just 19.6% of participants were listed as
having comorbid mental health problems but research suggests that approximately 85% of patients with depression will also experience significant levels of anxiety and comorbid depression occurs in up to 90% of patients with anxiety disorders (Gorman, 1996).

Additionally, the group may have acted on the presenting problem of participants whilst also affecting comorbid difficulties and symptoms below the clinical threshold that may serve to exacerbate the presenting problem. Rather than addressing one particular problem through a psychological intervention, a broader approach as employed in the group might allow skills to be generalised and applied to lower level difficulties. For example, the thought challenging skills developed by an individual with depression may also be applied to anxious cognitions and result in a decrease in comorbid anxiety. This is a positive outcome of the group but makes it difficult to identify the processes involved in the results.

It is possible that the situational elements of attending groups may have been beneficial. For example, the group in itself may have served to normalise the experience of participants leading to an improvement in distress and functioning. Wolfensberger and Tullman (1982) discussed the ways in which normalising can minimise the effect of feeling different to others in society. For the participants, being in a group setting with a number of other individuals experiencing similar difficulties to them might well have served this function and reduced psychological distress associated with feeling different and ‘abnormal’. This was not specifically measured in this study, but it may be useful to explore this in future research with a control condition.

Despite the limitations of the study, and the lack of clarity regarding the important processes involved, the results arguably offer greater ecological validity than other more robustly controlled research studies. The real-world sample of participants with the diagnoses, comorbidities and complexities typical of a secondary care mental health service suggests that trans-diagnostic CBT groups are a promising treatment option. In addition, these groups were run by practising clinicians from a range of disciplines within the service and the group facilitators followed a protocol devised by the clinicians based on their experience of working with individuals with a substantial range of diagnoses.

**Recommendations**

On the basis of the literature review and the evaluation of the group, the following recommendations have been made to improve effectiveness of the intervention and to allow the service to be more certain of the results obtained.
1. Participant demographic information should be gathered at the pre-group screening session in order for analyses of the effect of variables such as age to be explored. See Appendix F for a suggested interview guide.

2. A more robust assessment and recording of diagnosis and comorbidity should be conducted for participants attending the group. At present it is not possible to confidently conclude that the group intervention is equally efficacious across disorders because there is no reliable data regarding participant diagnosis. This could be obtained using a structured interview such as the Mini International Neuropsychiatric Interview (MINI; Sheehan et al., 1998) or the Structured Clinical Interview for DSM-IV (SCID-IV; First et al., 2002). Diagnosis should also be available from electronic patient records as recorded by a Consultant Psychiatrist; however, this is unlikely to provide information on comorbid difficulties.

3. Together with a more reliable measurement of participant diagnosis, disorder-specific outcome measures should be used in addition to the general outcome measures. This would allow for a comparison of effect sizes of the group intervention across disorders and diagnoses. The following disorder-specific measures were used for this purpose by Kristjánsdóttir et al. (In review):
   - The Panic Rating Scale (Panic disorder)
   - The Penn State Worry Questionnaire (GAD)
   - Liebowitz Social Phobia Scale (Social anxiety)
   - OCI-R (OCD)
   - Impact of Events Scale (PTSD)

Participants with florid psychotic symptoms or in a manic episode are not usually accepted on to the group programme and are more likely to participate outside of an acute episode where secondary anxiety or depression are the target symptoms of intervention. Therefore, the most appropriate measure for secondary symptoms should be used.

4. Participant feedback should be gained after each session. This will provide data about the experience of participants whilst it is still fresh in their minds rather than waiting until week 12 when it is more likely that details of early sessions will have been forgotten. Weekly feedback will provide more information regarding the useful and less useful aspects of each session. For example, the introduction of a psychological model of depression and the rationale for behavioural activation in session two may prove particularly useful for participants with affective disorders but may feel irrelevant and even discourage further attendance for those with anxiety disorders. It is recommended that the Session Impact Scale (SIS; Elliott & Wexler, 1994) be used at the end of each session. Kellett et al. (2007) selected the SIS to measure effectiveness of sessions within a group CBT intervention and adapted the original measure accordingly. For example, they removed items relating to the therapeutic relationship and used items from the two subscales relating to task and
interpersonal impacts. The authors also added an item concerning the usefulness of the materials from that session. The Cronbach’s alpha of the adapted scale was calculated as 0.95.

5. In groups to date only 50% of participants attended the booster session held one month after session 12. It is unclear if attendance has a significant effect on outcome measure scores as these are completed at session 12, (although there is no significant difference between the CORE-10 and WSAS scores of those who attended and those who did not). In order to determine if the booster is of clinical value outcome measures should be administered at session 12 and after the booster session. Ideally outcome measures should be repeated at a one-month (or longer) follow-up in order to gather data after the participants have had an opportunity to apply and further develop the skills learnt.

6. The Cognitive-Behavioural Therapy Skills Questionnaire (CBTSQ) should be administered at the pre-group screening interview and at the end of the group programme. This measure identifies changes in the frequency of which CBT skills are utilised by participants. The measure was developed by Jacob et al. (2011) and has subsequently been used by Webb et al. (2013) and Hundt et al. (2012). The CBTSQ has been found to have high internal consistency and to be both valid and reliable. This data will allow analyses to be conducted to identify any association between change in level of distress and change in CBT skills.
Part two: The PDSA cycle

Plan
The recommendations were presented to the service where it was decided which would be implemented in the subsequent group as follows:

1. The team agreed to collect more participant demographic data at the pre-group screening interview.
2. The team did not think that the time involved in administering a diagnostic screening tool was justifiable. However, they agreed to routinely collect information on diagnosis via review of the patient record.
3. Linked to the decision not to use a diagnostic screening tool, the team also chose not to administer disorder-specific outcome measures as it was felt that this would result in participants being asked to complete too many questionnaires. Instead they agreed to obtain pre- and post-group responses using the Generalised Anxiety Disorder-7 (GAD-7; Spitzer et al., 2006) and the Patient Health Questionnaire-9 (PHQ-9; Kroenke & Spitzer, 2002), that provide a measure of anxiety and depression respectively, in addition to the WSAS and CORE-10 as administered in previous groups.
4. It was decided that the SIS should also administered at all sessions.
5. The booster session was omitted due to poor attendance at the previous groups. Obtaining follow-up data from one month after the group was not felt to be feasible as some patients are discharged after the group.
6. The team agreed to administer the CBTSQ at pre- and post-group time points in order to track change in CBT skills.

Do
The group was delivered again in 2014, facilitated by a psychological therapist, a psychologist and two nurses, one of whom was involved in a trainee capacity. With the exception of the booster session being omitted the group ran according to the protocol outlined in Appendix E. It was hoped that the results would support the previous positive findings and allow for more robust analyses of the effects of different variables.

Study
The group started with nine participants. Five completed the group and provided pre- and post-group outcome measures. Participant characteristics and baseline outcome measure scores are displayed in Table three. Due to the very small sample size statistical analysis of the data and an intention-to-treat analysis were not possible.
Table three. Baseline participant characteristics of post-recommendation group (n=9).

Attrition

44.44% (n=4) of participants did not complete the group. This is higher than the attrition rate of the previous groups (17.6%). When the pre-group outcome measure scores were examined all participants exceeded the clinical cut-offs for the CORE-10, WSAS, GAD-7 and PHQ-9 suggesting severity of symptoms at the start of treatment was comparable to that of participants in the earlier evaluation.

Treatment efficacy

The mean pre- and post-group outcome measures for completers are displayed in Figure four. The post-group mean scores on all symptom outcome measures demonstrated a small decrease from pre-group scores.

Skills development

Mean pre- and post-group CBT skills of participants are displayed in Figure four (CBTSQ). The mean post-group scores show an increase from the mean pre-group score.

Session evaluation

The SIS was administered in only six of the 12 sessions due to some confusion with instructions. The results are shown in Figure five.

---

2 The clinical cut-off for the GAD-7 and PHQ-9 is 11 (moderately severe anxiety/depression).
Figure four. Mean pre- and post-group outcome measure scores for post-recommendation group

Figure five. Mean SIS scores

Due to the incomplete data set and inconsistency in the number of participants at each session further analysis of this feedback is not possible. Feedback forms were collected
anonymously to ensure that participants felt able to provide honest comments. However, this prevented an analysis of the effect of session ratings on other outcomes.

**What do these results show?**

The results described here were obtained from one cohort with a very small sample size. The attrition rate in this cohort was higher than in part one of this evaluation, further limiting the data analysis and conclusions that can be drawn. Although no statistical analysis could be performed, the mean scores for post-group symptom-related outcome measures all showed a decrease from baseline, and participants demonstrated an increase in CBT skills over the course of the group.

Unfortunately the difficulty identified in part one in examining the effect of the group on diagnosis type remained in part two. Although diagnosis was collected in a more routine manner from patient records, no further information about comorbidities was obtained and diagnosis was not based upon a standardized measure. It is therefore not possible to explore specific diagnoses (for example different anxiety disorders) and the three diagnostic categories used in part one were also used for the analysis in this secondary evaluation.

It is not possible to draw robust conclusions from the sample size presented in part two. However, the initial findings provide useful information about the implementation of the recommendations made following the analysis of the first five cohorts. For example, the inclusion of a range of questionnaires at pre- and post-group has provided a more detailed impression of the impact of the group. Using the PHQ-9 and GAD-7 outcome measures has resulted in information about the differential effect of the group on anxiety and depression. Further groups should continue to collect this information in order to explore any differential effects of the group on these symptoms. Further, the use of the CBTSQ provided useful information about the skills developed in the group. With the inclusion of future group data it may be possible to draw more robust links between outcomes and increased CBT skills.

Session-by-session feedback was obtained for half of the sessions. The feedback received indicated that participants who responded found the group helpful. Later sessions were scored more highly than earlier ones. However, as the feedback was obtained anonymously it is not possible to explore whether this increase was due to increased satisfaction towards the end of the programme or to other variables such as those participants who were less satisfied dropping out.

Furthermore, due to the feedback being obtained for only half of the sessions there is limited information about the usefulness of individual sessions. Future groups should obtain this feedback after each session and consideration should be given as to whether this information could be obtained for each individual rather than in an anonymous manner. This would allow an analysis of the impact of each session on an individual’s outcomes as well as providing
information about satisfaction with the group and any association with attrition or diagnosis. It seems that there was some miscommunication about the session feedback that may have led to the confusion over the frequency at which it was administered. In previous groups feedback was collected at the end of the group programme and it seems that the change to session-by-session feedback was not communicated to all facilitators. This meant that some facilitators administered the feedback forms after each session whilst others did not.

With the exception of the session feedback the recommendations that were implemented provided useful additional information about the effectiveness of the group. The recommendations that the team chose not to implement, such as the use of a standardized diagnostic tool for recording the diagnoses and comorbidities, were those that would substantially increase the time demand on the staff involved and were deemed unnecessary for the routine clinical delivery of the intervention. However, it is important that the measures and procedures that have been adopted are administered in a routine fashion. In order to ensure this a review of the measures administered and data collected should be made during each supervision session. This will help to ensure that all facilitators are delivering the intervention in a standard way and regularly reviewing the session feedback will mean that comments of patients can be acknowledged and acted upon, rather than waiting until the end of the intervention to see what could have been done differently.

Overall, the post-recommendation trans-diagnostic CBT group has demonstrated modest reductions in symptomatology and increases in functioning. The recommendations that were implemented provided more information about the changes associated with the group, specifically around symptoms of depression and anxiety and the development of CBT skills. The results of the initial evaluation suggest that the intervention is an effective treatment option for individuals under the care of the secondary care mental health team, irrespective of diagnosis, and should continue to be available in the future to individuals in this area. Furthermore, the initial positive findings provide justification for this intervention to be available to individuals in other areas receiving care from mental health services.

Act

The post-recommendation group supports the initial findings by repeated demonstration of an apparent trend for improvement for those participating, including on newly used measures of depression and anxiety, although sample size would need to be bigger to assess statistical significance. Therefore, the additional information and outcome data should continue to be collected from future group programmes. The team should also continue to collect session-by-session feedback from each session in order for a more thorough investigation of the mechanisms of change within the group.
The recommendations detailed methods for improving future evaluations of the group. This was important because only by obtaining more detailed and specific information about the positive findings could the actual delivery of the group be considered and potentially improved. Unfortunately some recommendations were not implemented, meaning that the PDSA cycle should continue. Once further group data has been collected an additional evaluation should be conducted in order to investigate more thoroughly the effect of the group.

Journal submission
This review will be submitted to the Journal of Personality and Individual Differences. This journal was chosen due to its publication of other articles exploring the role of thinking and beliefs in violent offending (Appendix Q).
Introduction

Violence poses a significant problem for those directly involved, such as the victim, the perpetrator and their families, and for society as a whole, placing a burden on services including the criminal justice system and the NHS. Most recent reports estimate that there were 1.3 million violent incidents in England and Wales between October 2013 and September 2014 (Office for National Statistics, 2014). Gilligan (2001) suggested that a crucial step in the prevention of violence was gaining an understanding of its underlying causes and there is a growing body of literature aiding the development of this understanding.

A central distinction that has guided theories of violence in recent years has been that of instrumental and affective (otherwise referred to as reactive, hostile or angry) violence. Bushman and Anderson (2001) described affective aggression as impulsive and driven by desire to inflict harm, whereas instrumental aggression is premeditated and motivated by the pursuit of a different goal, for example obtaining money. They went on to outline and critique three differences suggested to be key between affective and instrumental aggression; the primary goal being harm or a means to another end, the presence or absence of anger, and the extent to which planning and premeditation is involved. Bushman and Anderson (2001) argued that these factors lead to a dichotomous view of aggression and violence that prevents consideration of the commonalities of affective and instrumental aggression. Instead, Anderson and Bushman (2002) proposed that the important distinction lies in whether inflicting harm constitutes a proximate or an ultimate goal. They suggested that intent to harm is a necessary part of any violent act but what differs is whether this harm forms the ultimate goal (such as assault) or a proximal outcome in the pursuit of a different ultimate goal (such as robbery).

The distinction between instrumental and affective aggression and violence is important because true instrumental aggression and violence has the potential to be motivated and understood in numerous ways, not necessarily with violence at the core. For example, an individual may commit an armed robbery simply to enrich him or herself, and the theories and models used to understand affective violence would not be applicable. As a result, psychological theories and understandings of violence tend to focus on affective violence, where intent to harm is an ultimate goal, rather than instrumental violence.

One of the central factors in the development of cognitive theories of non-instrumental violence has been anger. Novaco’s cognitive behavioural model of anger proposed that cognitive processes mediate the link between a trigger event and feelings of anger which can in turn lead the individual to act in an aggressive manner (Novaco, 1978). Novaco and Welsh (1989) suggested that the cognitive processes involved in the association between an event and the experience of anger can be described in terms of five information-processing biases: attentional cueing, perceptual matching, attribution error, false consensus and anchoring effects. Novaco suggested that these cognitive processes all contribute to the way in which events are
(mis)interpreted in a manner that can lead to anger and violence (Novaco, personal communication, 24 July, 2015).

There has been considerable further research into the association between anger and violence with findings that anger predicts aggression in a range of samples including young offenders, non-violent adults, mentally-disordered offenders and incarcerated offenders (Loza & Loza-Fanous, 1999). As a result, anger management using cognitive-behavioural approaches has been widely provided in prisons and forensic settings. However, evidence for the benefits of anger management for violent individuals is inconclusive. Meta-analyses in the field (Beck & Fernandez, 1998; Edmondson & Conger, 1996) have been criticised for basing their conclusions on some studies that used normative samples, including school children, and spurious uses of effect sizes and statistical analyses (Walker & Bright, 2009a). In addition, the link between anger and violence itself has been disputed (Loza & Loza-Fanous, 1999) and these findings led Walker and Bright (2009a) to suggest that anger management for violent offenders may be both ineffective and irrelevant. Novaco, an early proponent of anger management, considered that as a normal human emotion, anger was neither necessary nor sufficient for violence (Novaco, 1994).

Shanahan, Jones and Thomas-Peter (2011) highlighted that although Novaco and Welsh (1989) offered various cognitive processes for consideration in the development of anger relating to interpretations made by an individual about their internal, external or imagined experience, the theory fails properly to consider how high or low self-worth might be involved in unhealthy anger. They went on to evaluate the relationship between unhealthy anger, shame and self-worth and highlighted the importance of low self-worth and high feelings of shame in the development of anger, proposing that, in line with Beck (1999), anger may act as a defence against these negative self-concepts.

There are conflicting ideas about the role of self-worth or self-esteem in violent behaviour with some suggestions that low self-esteem is associated with violence whilst others propose that high self-esteem constitutes the greater risk factor. Salmivalli (2001) and Baumeister, Bushman and Campbell (2000) highlighted that many authors have referred to a link between low self-esteem and aggression but without basing this claim on any empirical evidence. Salmivalli (2001) suggested that this may be due to it seeming anomalous to think that individuals who feel good about themselves would act in a violent or aggressive manner to others. However, Baumeister et al. (2000) disputed this popular belief and suggested that low self-esteem is more likely to lead people to avoid risk, to submit to external influence and to be confused about their identity; factors that they said contradicted patterns and characteristics of violent individuals. Instead, they cited an earlier review (Baumeister, Smart, & Boden, 1996) suggesting that high-self esteem and feelings of superiority were consistently associated with violence. Baumeister et al. (2000) did not propose that simply the presence of high self-esteem
is a causal factor in violence, but that the danger arises when high self-esteem is combined with an ego-threat; the threatened egotism hypothesis. This suggests the violent individual’s high self-esteem to be fragile and vulnerable to underlying self-doubts and fears of losing esteem, and so when threatened leads to attack.

This argument seems to link to another important concept in exploration of self-worth and violence; the stability of high self-esteem. Kernis, Grannemann, and Barclay (1989) found that those with unstable high self-esteem were more aggressive than controls, whereas those with stable high self-esteem were not. Kernis, Cornell, Sun, Berry, and Harlow (1993) discussed this unstable subgroup of individuals with high self-esteem and suggested that they are particularly prone to violence and aggression due to their self-concept being fragile and vulnerable and thus particularly sensitive to external insult and provocation. With these findings in mind, Salmivalli (2001) suggested that unstable high self-esteem may actually be falsely-inflated, appearing high but concealing a low sense of self-worth. This potentially explains why the instability of an individual’s high self-esteem represents such an important distinction in terms of the association with violence and offers an alternative view to Baumeister’s threatened egotism hypothesis (Baumeister et al., 1996). This is consistent with the literature exploring the concept of narcissism. Tafarodi and Ho (2006) discussed the dissociation of conscious and unconscious aspects of self-worth and linked narcissism to low implicit and high explicit self-esteem, whereby an external portrayal of the self as superior masks an internal sense of low self-worth. Baumeister et al. (2000) also linked narcissism to high but unstable self-esteem, suggesting that this construct is relevant to this debate.

Walker and Bright (2009b) systematically reviewed the evidence relating to self-esteem and violence and concluded that low, rather than high, self-esteem appears to be more consistently associated with violence. They also found preliminary evidence that narcissism is predictive of violence. Walker and Bright (2009b) used these findings, as well as their own clinical experience, to propose a cognitive model of violence with low self-esteem, disguised by falsely-inflated self-esteem, at the core.

This model links to the cognitive theory of emotion (Beck, 1976) which suggests that anger arises from the appraisal of situations in terms of someone having ‘broken the rules’; it is also informed by the cognitive model of self-esteem (Fennell, 1997). The Walker and Bright model is shown in Figure one and, as with other cognitive models, it postulates that one’s early experiences lead to the development of core beliefs. Often these are linked to the Beckian cognitive triad of the self, world and future, however, this model places particular emphasis on negative beliefs about the self (low self-esteem). Conditional assumptions (or ‘rules for living’) are then developed to try to defend against these beliefs and can serve to compensate for deeply negative self-appraisals through aggression, exaggerated displays of confidence and, seemingly, arrogance.
The model proposes that particularly important to violence are beliefs related to self-esteem, specifically of the self being vulnerable, weak or stupid, and conditional assumptions will manifest as strategies for portraying the opposite; the self as strong and to be respected (i.e. “If someone disrespects me I must fight to show that I am strong”). In this context a trigger could lead the individual to feel actual or threatened humiliation and/or disrespect, activating the core beliefs against which the individual unconsciously tries to defend. The grey pathway in Figure one represents the experience of real humiliation or disrespect and this, in the absence of other strategies, can quickly lead to a violent response. The black arrows indicate how the perception of a threat of humiliation or disrespect can result in the same response due to the influence of negative predictions and resultant anxiety. Finally, the dotted pathway represents a situation in which the individual perceives real or threatened humiliation or disrespect and experiences associated anxiety, but is able to resist a violent response. However, each pathway can result in the confirmation of the individual’s negative self-beliefs which reinforces thoughts around the necessity of a violent response to prove one’s strength; the dotted pathway, where violence is resisted, is suggested to lead to increased self-critical thinking linked to core beliefs and increased anxiety which feed back into the cycle and maintain a pattern of violent responding.

The model was developed based on the tendencies of violent offenders, noted during the authors’ clinical experiences, to draw extremely personal and negative meanings from seemingly innocuous social situations; Walker and Bright (2009b) suggested that the situations and insults that are most congruent with one’s negative beliefs are most hurtful and humiliating. Therefore if a situation, whether real or perceived, taps into a negative aspect of the self that the individual associates with fear, shame or dislike, they are more likely to react in a manner that protects the self from further insult. A violent response serves the double purpose of protecting and maintaining a sense of self-worth by fighting and not backing down, whilst also punishing the victim for the humiliation they caused or threatened to cause.

Although the model could be criticised for not focussing on affect, and in particular the experience of anger, it can nevertheless be seen as complementing, rather than contradicting, the extensive research in this field. From the perspective of Novaco’s theorising (Novaco & Welsh, 1989), the Walker and Bright model of violence could be taken as elaborating on and more clearly specifying the attribution errors suggested as being an important cognitive process involved in the development of anger and subsequent aggression and violence. As such the model focuses on these cognitive processes; should it stand up to empirical testing it may then benefit from further clarification regarding the combining of cognitive and affective theories of violence.

Cognitive theories have been proposed in other areas of psychology and the applicability of the different stages explored through studies of phenomenology. For example,
the cognitive model of panic disorder was proposed (Clark, 1986) and its components explored through experimental studies (Clark et al., 1988; McNally & Foa, 1987), the findings of which informed cognitive-behavioural treatment of panic disorder. In a similar process, research now needs to be conducted to explore the applicability of the cognitive model of violence. As with other cognitive models, a key element appears to be underlying core beliefs and assumptions and the subsequent appraisals that they influence. It is possible that the conditional assumptions suggested as being important in this model lead individuals to be hypervigilant to humiliation, disrespect and provocation and, therefore, for subsequent interpretations of events to be skewed. Identifying and understanding cognitive processes that may be involved in violent behaviour is crucial for the development of strategies to challenge cognitions related to violence and ultimately to prevent violence itself.

Using research design and methodology from a study that investigated the role of interpretation in the cognitive model of panic (Clark et al., 1997), the Violence Interpretation Questionnaire (VIQ) was developed to explore the importance of negative interpretations of social situations in violent behaviour. Negative interpretations in this context refer to appraisals that indicate the individual perceives some disrespect or violent intent from another person. Although there are other possible negative interpretations that can be made these are the main appraisal styles suggested by the model to be particularly implicated in violence. Therefore, for the purpose of this study, ‘negative interpretation’ is used to refer to these types of appraisal. It is hoped that gaining an understanding of the nature of interpretations made by violent men will provide clinically useful information to inform assessment and treatment strategies for violent offenders. The section of the model tested in this study is highlighted in Figure one.

The primary hypothesis of this study is that violent offenders will interpret ambiguous interpersonal situations, as assessed using a new measure (VIQ), more negatively than non-offenders, but will not show this pattern for non-social control items. It is also predicted that negative interpretations of interpersonal situations will correlate with violent thinking and with narcissism. In addition, this study will seek to explore the concurrent validity of the VIQ with another measure of violent thinking.
Figure one. A cognitive model of violence (Walker & Bright, 2009b).
Method

Participants

Two groups of adult male participants were recruited: a sample with convictions for violent offences from the National Probation Service \((n=17)\) and a normative online sample without a known offending history \((n=97)\). No incentives were provided for participants. The online sample was subsequently split into those who endorsed any item on the Self-Report Violence Scale \((n=28)\) and those who did not \((n=69)\); participants who scored one or more were considered to be aggressive having reported committing at least one illegal violent act in the previous 12 months. This resulted in three separate groups referred to here as the offender group, aggressive control group and non-aggressive control group.

Inclusion criteria

For the offender sample the following inclusion criteria were applied: a) male; b) over 18 years old; c) statutory offender (i.e. currently on a probation order); d) living in the community (not in prison); e) convicted of at least one violent offence\(^1\); f) no previous convictions of sexual offences; g) no diagnosed learning disability; h) not suffering from serious mental health problems as reported by probation officer; i) not deemed by probation officer to be too high risk to meet with a lone female researcher.

Participants in the online control sample were required to be male and over 18 years old. The online sample was anonymous allowing for no verification of the demographics or offending histories.

Women were excluded due to various gender differences including those in the nature of violence and aggression (see Motz, 2008).

Measures

The VIQ (Appendix G) was developed for this study and comprises 22 items that assess how an individual interprets ambiguous interpersonal situations and non-social events, and how they would anticipate responding. The questionnaire design and scoring is based upon the Bodily Sensations Interpretation Questionnaire (BSIQ) used in a study exploring interpretations in individuals with panic disorder (Clark et al., 1997) and the VIQ uses the format of the BSIQ wherever possible. Ideas for situations were generated and discussed between authors to identify those that could potentially be construed as negatively self-referent.

\(^{1}\)Any uncertainty about the definition of ‘violent offence’ was discussed with the probation officer. Violent offences reported here were committed under the Offences Against the Person Act (1861), Public Order Act (1986) or under common law (i.e. murder).
The VIQ lists 11 ambiguous interpersonal situations that may be appraised as positive, neutral or negative. Following each item are the questions ‘why?’ and ‘what would you do?’ inviting the participant to provide their interpretation and most likely behavioural response for the situation. In accordance with the methodology of studies using the BSIQ these open responses are not analysed (Clark et al., 1997). In the initial study using the BSIQ, open-responses were rated as being negative, neutral or unclassifiable by two independent raters. These ratings, however, were found to provide no additional information to the rankings and were time-consuming to complete. Consequently, the rating of open responses was not conducted in further studies using the BSIQ and, therefore, the function of the open responses of the VIQ is solely to prompt participants to think through the situation and their likely interpretation and behaviour. Participants then turn the page and rank three possible explanations in terms of likelihood. The offered explanations comprise one negative and two neutral options. The negative interpretations are based on one of two categories: perceived violent intent or perceived disrespect and, according to the cognitive model, these two broad categories are hypothesised to be linked to core beliefs of violent individuals. Participants are also asked to choose the most likely way in which they would respond from three options that comprise one aggressive and two either assertive or passive options. The format of the behavioural response section differs from the BSIQ; questions about behavioural responses are presented alongside interpretation questions for brevity and simplicity.

The 11 control items relate to non-social situations that may threaten self-esteem and control for the potential threat to validity of participants responding in a generally negative manner rather than specifically in interpersonal situations. Negative responses to all items may indicate global low self-esteem rather than a specific cognitive bias in interpersonal situations. Control items are presented in the same format as the interpersonal items. The suggested behavioural responses will not be included in the analysis; this section is included to blind participants to control items.

*VIQ Scoring (Appendix H)*

Scores from the ranking of possible explanations are given depending on whether the negative option is ranked first, second or third, with a score of three, two and one respectively. Total interpersonal and non-social scores are then calculated with a hypothetical range of 9-27.

---

2 Consideration was given to possible different interpretations but it was found that they could always be covered by one of the two broader categories of perceived violent intent or disrespect (i.e. perceived to have been taken advantage of would fall into perceived disrespect). Future research will use thematic analysis techniques to identify themes in open responses that will further validate the use of these categories.
Behavioural responses are scored for interpersonal items; aggressive actions are summed into a total aggression score (range 0-9).

**VIQ Pilot**

The VIQ was piloted with six men without an offending history to check acceptability and ceiling and floor effects. This resulted in four questions being omitted; two interpersonal items were removed due to ceiling and floor effects and two non-social items were removed to allow for equal numbers of item type. Time taken to complete the VIQ ranged from 20-30 minutes. The final study protocol was then piloted with two offenders who both found participation to be acceptable and raised no difficulties or concerns.

**VIQ psychometric properties**

The VIQ is a novel measure and, therefore, its psychometric properties will be investigated. The internal consistency and distribution of the data on interpersonal items of the VIQ will be analysed and reported.

**The Self-Report Violence Scale – Prison Sample – UK** (SRVS; Mak, 1993) was originally designed for use with Australian adolescents but has been revalidated for use in Western Australia (Carroll, Durkin, Houghton, & Hattie, 1996) and with adult clinicians, criminal justice professionals and a sample of 785 adolescent students in the UK (Walker, 2005). A nine-item violence scale was used in a recent study with violent and non-violent adult samples and showed significant correlations between offending status and self-reported level of violence, suggesting that the measure is sensitive to differences in levels of previous violence in offender and non-offender populations (Walker & Bowes, 2013). This nine-item scale was administered in the current study. Upon further review of the scale one item (related to bullying) was omitted; unlike the remaining eight items this did not constitute an illegal violent act and if endorsed would not necessarily reflect an individual with violent tendencies (see Appendix I).

**The MVQ** (Walker, 2005) assesses an individual’s beliefs and rules relating to violence and has been shown to be a valid and reliable measure of violent thinking that significantly relates to self-reported violence and official records (Walker & Bowes, 2013). The MVQ is a 54-item questionnaire that invites participants to respond ‘true’ or ‘false’ to a range of cognitions and beliefs that violent individuals are thought to use, for themselves and others, as justification of their violence. The MVQ comprises of two subscales; machismo and acceptance and a significant positive correlation has been found between scores on the machismo subscale and self-reported violence. The acceptance subscale can also indicate socially-desirable responding.
The Narcissistic Personality Inventory (NPI-16; Ames, Rose, & Anderson, 2006) is a short version of the NPI-40, a 40-item forced-choice measure of narcissism (Raskin & Hall, 1979; Raskin & Terry, 1988). Ames et al. (2006) found the NPI-16 to be valid and predictive of the longer NPI-40 and, as such, they recommend its use in situations where a shorter measure is appropriate. This measure of narcissism was administered to assess a component of self-esteem. Self-esteem is clearly implicated in the model but assessing this construct is complicated by a pattern of responding hypothesised to disguise low self-esteem through falsely inflating the view of the self, thus appearing as high self-esteem. Walker and Bright (2009b) suggested that self-esteem may be falsely inflated either consciously or unconsciously, with the former often identified as arrogance whilst the latter more commonly considered a narcissistic defence. With the inherent difficulties in measuring self-esteem, the NPI was included to explore whether this type of false inflated self-esteem is linked to violent thinking.

The Paulhus Deception Scale (PDS; Paulhus, 1998) measures two facets of socially desirable responding; impression management (IM) and self-deceptive enhancement (SDE) and can be used as a validity check. IM represents a conscious effort to portray oneself in a more, or less, socially desirable manner whereas SDE explores an unconscious bias to respond in a socially desirable manner and extreme scores on this scale are closely related to narcissism. For research use, the PDS manual recommends examining IM scores and provides thresholds for likely invalid responding. Lanyon and Carle (2007) explored the internal and external validity of the PDS and found that it is an appropriately valid measure to use with forensic populations. The PDS consists of 40-items and invites participants to respond on a five-item Likert scale indicating how true of themselves they consider a particular statement to be. The PDS was administered in the offender group as a validity check. IM scores above the cut-off for ‘faking good’ (>8) and below the cut-off for ‘faking bad’ (<2) indicate that the participant may have responded in a socially-desirable manner and the data obtained using other measures should be interpreted with caution.

Procedure

Ethical approval was obtained from the National Offender Management Service Research Committee (2014-232) and the University of Bath Psychology Ethics Committee (14-099).
Violent offender sample

Initially, all probation officers in a specialist team in the probation service who manage the most high-risk violent offenders were asked to identify all individuals on their caseloads who fitted the inclusion criteria. When it became clear that insufficient numbers were available in this team, in part due to the number excluded on the basis of sexual offending and the high prison recall rate, probation officers in the general probation service were also approached. Probation officers gave individuals fitting the criteria an information sheet about the study and asked if they would be willing for the researcher to contact them (Appendix J). Those who gave consent were contacted and a meeting was arranged.

Participants met the researcher either at the police station where they were usually seen by their probation officer or in an approved probation hostel (where they were residing). Participants provided informed, written consent (Appendix K) and some demographic information (Appendix L). They were then given the choice of completing the five questionnaires independently but with the researcher present, or to go through the study together with the researcher reading items aloud and writing responses. The majority of offenders opted for the researcher to provide such assistance mainly, it appeared, due to difficulties with reading and writing, or lack of confidence in these things. All responses were confidential and anonymous, with the exception of any information that indicated a risk to the safety of the participant or others, or related to a previous offence not known to the probation service or police. In such cases only information directly relating to this risk was disclosed to the individual’s probation officer. Scanned copies of consent forms were uploaded to the probation record of participants and the researcher met with a member of probation staff to obtain details of previous convictions, custodial sentences and risk profile scores (Appendix M).

Aggressive and non-aggressive control samples

The control groups were a sample of convenience recruited online. Professional and personal contacts of the researcher were asked to participate in the study and to share this with their own contacts. Social media networks including Facebook and Twitter were utilised to ensure that participants represented a wide range of ages, demographics and social circumstances. Participants were provided with a link to an online version of the study using Bristol Online Surveys where the information sheet was presented and consent was gained using tick boxes. Participants were able to contact the researcher with any queries or concerns prior to completing the study. Responses were anonymous.
Statistical analyses

Power considerations

The VIQ was a new measure and therefore a power calculation was conducted based on a recent validation of the MVQ with adult offenders and non-offenders (Walker & Bowes, 2013) in which the effect size for the relationship between machismo and self-reported violence was $d=1.2$. Originally a somewhat different design was planned for this study and, using this effect size, a calculation based on the intended primary analysis (two-way between-participant analysis of variance) indicated that a minimum sample size of 40 (20 per group) would have 96% power to detect differences between the two groups at a 0.05 two-tailed significance level. Although it became clear that recruitment of the originally proposed comparison group (non-violent offenders) was impractical and the study changed in design, the sample size suggested here was retained.

Missing data

There were a small number of missing data points in the offender group. Four omitted one item each on the VIQ and nine omitted between one and three items on the PDS. Missing PDS data was pro-rated according to the manual and missing VIQ data was pro-rated using this same method.

All data were stored anonymously and securely. Responses were entered, coded and analysed using SPSS Version 19.

Results

Demographic information of the three groups is displayed in Table one. One-way analyses of variances were carried out and found a significant effect of group upon both age ($F_{[2, 111]}=5.22, p<0.01$) and education ($F_{[2, 111]}=22.92, p<0.01$). Post-hoc tests revealed that age differed significantly between the non-aggressive control and both aggressive control and offender groups ($p<0.01$) but no significant difference was shown between the aggressive control and offender groups ($p>0.05$). There were significant differences in education level between the offender group and both aggressive and non-aggressive controls ($p<0.01$) but not between the two control groups ($p>0.05$).

Note: ‘Convictions’ indicate number of court appearances at which participant was convicted; ‘offences’ indicate number of separate offences for which the participant was found guilty; ‘offences against the person’ represent violent crimes detailed in the Offences Against the Person Act (1861), OVP=OASys Violence Predictor (Howard & Dixon, 2012) provides a percentage likelihood of violent reoffending based upon the percentage of a group with the same offending profile who would be reconvicted within one and two years respectively (based on previous samples and reconviction data).

Ethnicity was divided into Caucasian vs non-Caucasian for the purposes of analysis; there was no significant association between group and ethnicity ($\chi^2(2)=3.70, n=114, p>0.05$). There was a significant association between marital status and group ($\chi^2(3)=25.34, n=114, p<0.01$) with proportioned Chi square tests indicating that there were more participants who were single in the offender sample than in the aggressive control ($\chi^2(1)=4.71, n=45, p<0.05$) and in the non-aggressive control group ($\chi^2(1)=23.93, n=86, p<0.01$). There were also more single participants in the aggressive control compared to the non-aggressive control group ($\chi^2(1)=8.56, n=97, p<0.01$). The association between group and employment status was also significant ($\chi^2(2)=38.85, n=114, p<0.01$) and this was accounted for by the greater number of unemployed participants in the offender group than in the aggressive control ($\chi^2(1)=12.01, n=45, p<0.01$) and
non-aggressive control group ($\chi^2_{(1)}=35.19, n=86, p<0.01$). There was not a significant difference between the control groups ($\chi^2_{(1)}=2.15, n=97, p<0.05$).

Offending histories, number of custodial sentences, risk scores and PDS scores of the offender group are shown in Table two. The mean score on the PDS IM subscale was below the threshold that indicates results may be invalid (see Appendix N for further details).

**Preliminary psychometric properties of the VIQ**

*Internal consistency*

Internal consistency was evaluated for interpersonal items only in the offender and aggressive control groups because variance in non-aggressive control participants was likely to be very low. The Cronbach’s alpha for the offender and aggressive control participants ($n=45$) was 0.73, which represents good internal consistency for a subscale of nine items.

Non-social control items were not analysed because they were specifically chosen to be of a negative nature but without a consistent theme; they were there to control for negativity in interpretations across a range of domains.

*Normality of data*

The two key dependent variables (VIQ interpersonal and non-social items) were tested for normality using the Shapiro-Wilk (SW) statistic which indicates that, as expected, the distribution for offender and aggressive control participants did not deviate from normality; $SW=0.93$, $df=17, p>0.05$, $SW=0.93$, $df=28, p>0.05$ respectively. The non-aggressive control participants did differ from normality ($SW=0.85$, $df=69, p<0.05$). The distribution problem for non-aggressive controls is largely due to a positive skew with the majority of scores being very low.

*Primary variable: VIQ interpretations*

These data were analysed using a mixed model analysis of variance using one grouping factor (offender, aggressive controls and non-aggressive controls) and one within-subjects variable (VIQ item type; interpersonal vs non-social situations). There was a significant main effect of item type ($F_{[1,111]}=7.07, p<0.01$) and of group ($F_{[2,111]}=3.54, p<0.05$). These effects were modified by a significant item type x group interaction ($F_{[2,111]}=7.58, p<0.01$) as shown in Figure two.

Due to the significant interaction a simple main effects analysis was conducted using one-way analyses of variance for each item type. These showed a significant main effect for interpersonal VIQ items ($F_{[2,111]}=9.86, p<0.01$) but not for non-social items ($F_{[2,111]}=0.1, p>0.05$).
Post-hoc tests (Fisher’s Least Significant Difference; LSD) were therefore conducted for interpersonal VIQ items only and revealed that the non-aggressive control group was significantly different to both the offender and aggressive control groups ($p<0.01$) but the offender and aggressive control groups did not differ significantly ($p>0.05$). Paired samples $t$-tests were carried out to examine within-group responses on interpersonal and non-social VIQ items. In the offender group there was a significant difference between item types ($t_{16}=-2.36$, $p<0.05$) showing that this group made more negative interpretations of interpersonal items than they made of non-social items. The same pattern of results was found in the aggressive control group ($t_{27}=-2.47$, $p<0.05$) but not in the non-aggressive control group ($t_{68}=1.81$, $p>0.05$) which showed no significant difference between interpersonal and non-social VIQ items.

![Figure two. Interaction of group and VIQ item type](image)

**Secondary variable: VIQ Aggression**

A one-way analysis of variance was carried out to investigate the anticipated behavioural response of participants in the three groups on interpersonal items (aggression score). There was a significant effect of group ($F_{[2,111]}=11.21$, $p<0.01$). Post-hoc tests (LSD) revealed significant differences between the offender group and both aggressive and non-
aggressive control groups ($p<0.01$) but no significant difference between the aggressive and non-aggressive control groups ($p>0.05$). These results show that the aggression scores of the offender group were significantly higher than both the aggressive and non-aggressive control groups (see Table three).

**Further analyses**

**MVQ**

MVQ machismo and acceptance scores are shown in Figure three. A one-way analysis of variance was carried out and found a significant effect of group on MVQ machismo ($F_{[2,111]}=16.13$, $p<0.01$) and acceptance scores ($F_{[2,111]}=7.89$, $p<0.01$). Post hoc tests (LSD) revealed that MVQ machismo scores of non-aggressive controls were significantly different to those of both aggressive controls and offenders ($p<0.01$); there was no significant difference between offender and aggressive controls ($p>0.05$). For MVQ acceptance scores a significant difference was found between aggressive and non-aggressive controls ($p<0.01$) but not between the offender group and the aggressive and non-aggressive controls ($p>0.05$).
A stepwise linear regression analysis was completed to explore the relationship between MVQ machismo and VIQ interpersonal item scores across the three groups. Tests indicated that multicollinearity was not a concern (MVQ machismo tolerance=1.0, VIF=1.0). A significant effect was found ($F_{[1, 112]}=53.0, p<0.01; R^2=0.57$). To investigate this effect further the relationship was considered within groups using simple correlations, which found relationships between MVQ machismo and VIQ interpersonal scores in both the non-aggressive controls ($r=0.38, n=69, p<0.01$) and in the offender group ($r=0.87, n=17, p<0.01$). However, there was not a significant correlation in the aggressive control group ($r=0.12, n=28, p>0.05$).

**NPI**

A one-way analysis of variance was completed for NPI total scores (displayed in Table three) which showed a significant effect of group ($F_{[2,111]}=9.77, p<0.01$). Post-hoc tests (LSD) revealed a significant difference between the non-aggressive and aggressive control groups ($p<0.01$) and between the offender and aggressive control groups ($p<0.01$) but not between the offender and non-aggressive control groups ($p>0.05$). It is possible that this resulted from different modes of administration between the offender and control groups with the offender group responding in the presence of the researcher as opposed to anonymously online. No significant correlations were found between NPI scores and VIQ interpersonal or non-social item scores across the three groups.
Discussion

This study compared violent and non-violent men in order to evaluate predictions from the cognitive model of violence (Walker & Bright, 2009b) using a novel measure of interpretations of interpersonal situations and anticipated behavioural responses. Three groups were compared; violent offenders recruited from the probation service (offender group) and two control groups recruited online, one that self-reported violence in the previous 12 months (aggressive control) and the other self-reporting no violence (non-aggressive control). The analysis showed that both the offender and the aggressive control group were more likely than the non-aggressive control group to interpret interpersonal situations negatively. There was no difference in interpretations of non-social events indicating that this effect was specific. It was surprising to note that the offender group did not differ from the aggressive controls on the interpersonal interpretation variable, but they did, however, differ on what they said they would do, with the offender group predicting significantly more violent responses that the two control groups who did not differ.

These findings are consistent with those from studies of the MVQ (Walker & Bowes, 2013; Walker & Gudjonsson, 2006). The interpretations of interpersonal situations made by offenders and aggressive controls on the VIQ were more negative than those of non-aggressive controls, reflecting the finding that offenders scored higher on the MVQ machismo subscale than non-offenders (Walker & Bowes, 2013). Furthermore, there was a significant positive correlation between MVQ machismo and VIQ interpersonal scores for offenders and non-aggressive controls. This provides some concurrent validity for the VIQ. MVQ machismo did not differentiate offenders and aggressive controls, which is surprising. VIQ interpersonal scores also did not differentiate these two groups, however, the aggression score did. This means that the VIQ adds something to the MVQ by better discriminating the aggressive controls from high-risk violent offenders.

This study was carried out as a test of a part of the cognitive model of violence related to self-referent interpretations of events based on negative self-concept. Although other studies have looked at the role of surface level cognitive rules (Walker, 2005; Warnock-Parkes, Gudjonsson & Walker, 2008; Walker & Bowes, 2013), this is the first empirical study of the more central components. The results are consistent with the theory in that specific respect; violent individuals (offenders and aggressive controls) interpreted interpersonal situations more negatively than non-aggressive controls as predicted. A particularly interesting finding was that of the aggressive control group who interpreted interpersonal situations similarly to offenders but predicted that they would respond similarly to non-aggressive controls. This suggests that there may be a further factor mediating the relationship between negative interpretation and violent response that comes into play after the appraisal is made, such as impulsivity or ability to tolerate negative interpretations and humiliation. Another important factor that needs to be
considered but was not explored in the present study is the role of anger. Although not explicit in the Walker and Bright cognitive model of violence there is evidence to suggest that anger may arise as a result of interpretations and may play a mediating role in the development of violence. For example, Holbrook et al. (2014) demonstrated that adults experienced higher levels of anger when they perceived another to have greater capacity to inflict harm (i.e. when holding a knife) compared to the perception of less harm (i.e. not holding a knife). This suggests that the interpretation made about another person influences the individual’s emotional experience. Once aroused, this anger may serve to mediate the subsequent violent behaviour through energising the individual or over-riding the inhibitory control of the individual (Novaco, personal communication, 24 July, 2015).

The findings of the current study are nevertheless consistent with the Walker and Bright model of violence and the proposition by Beck (1999) that the beliefs of the perpetrator of violence are key and that these beliefs may lead to subsequent misinterpretation of others’ behaviour as antagonistic or disparaging which, in turn, can lead to feelings of vulnerability. However, neither this study nor the model provide an explanation of the other mediating factors involved in the pathway from (mis)interpretation to the act of violence. The conclusions of a review by Elison, Garofalo, and Velotti (2014) may provide some useful considerations to this omission, such as the suggestion that shame is experienced following a relational devaluation and this leads to anger and aggression as a defence against this feeling. Clearly anger is potentially a very important mediating factor in the development of affective violence and further consideration needs to be given to how it might be incorporated into that theory. Future research into the Walker and Bright cognitive model and its possible elaboration should include this, as well as into other factors such as shame. DiGiuseppe and Tafrate (2007) argued that clinical models of anger failed to adequately account for why low self-worth can lead to anger rather than depression. This argument could equally well be directed at the cognitive model of violence; further research should seek to explore the mediating factors, such as anger, that lead the individual to externalise and attack rather than to internalise and experience depression.

Limitations

The study is slightly underpowered; the original power calculation identified that a sample of 20 offenders was required but it was possible to meet with only 17. It also cannot be assumed that the offender sample is representative as, although probation officers were asked to consider all offenders on their caseloads, the recruitment strategy involved them selecting offenders who they deemed appropriate and sufficiently low-risk. However, representative sampling in a forensic population is inherently difficult as it could be argued that higher-risk individuals with more anti-social beliefs and tendencies are less likely to volunteer. Indeed,
several offenders stated that previously they would have been unlikely to participate and their responses would have been more negative and more violent.

The difference between data collection methods of the groups is also important to note. It was originally planned that the control group would be recruited from the probation service but this was not possible and it was necessary to substitute this with an anonymous online sample.

Linked to these differences in mode of study administration is the issue of socially-desirable responding. The PDS scores of the offender group suggested that some participants responded in a manner that minimised their socially-undesirable tendencies. This was reflected in the elevated IM scores for some offenders that exceeded the level indicating possible ‘faking good’. Furthermore, this manner of responding was also apparent on MVQ acceptance scores; although not significantly different between the offender and the two control groups, there was a significant negative correlation between IM and MVQ acceptance scores, suggesting that offenders with higher ‘faking good’ scores on the PDS were more likely to minimise their acceptance of violence on the MVQ. It can therefore be hypothesised that the offender group responded in a socially-desirable manner on other variables. Unfortunately this is difficult to avoid, particularly in a forensic sample who may have been uncomfortable disclosing their true thoughts and beliefs about violence. Although confidentiality was strongly emphasised participants were also informed of the researcher’s duty to share any new disclosures of serious violent offences.

**Research implications**

The findings of this study should be replicated with a larger sample and using a comparison of violent and non-violent offenders who would be more likely to match on demographic and other characteristics. As indicated above the cognitive model of violence suggests that self-esteem is a moderator variable in violence and this was not measured here. It is difficult to accurately assess self-esteem, however, further investigation should be made to explicitly identify if self-esteem is implicated.

This study, and particularly the results of the aggressive controls, raises new questions about the cognitive model of violence. Although this group was identified through their endorsement of violent behaviours there was something about them that had so far prevented them from committing serious violent offences (or from getting caught). This group, and identifying mediating factors that would explain the differences in violent behaviour between them and the offenders, in particular the role of anger, should be afforded further research attention.
Clinical implications

The VIQ aggression scores produced the interesting finding that the aggressive control participants interpret interpersonal situations in the same way as the offender group but that their behavioural response would be different. The VIQ adds to information gained by the MVQ, one of the main measures of violent thinking (Bowes & McMurran, 2013), and, following further research and validation, the VIQ has the potential to be a useful clinical tool to inform risk assessments and outcomes of interventions.

In terms of intervention and treatment, these findings support the use of cognitive-behavioural approaches in working with violent individuals on attribution errors. Furthermore, although not investigated here, the findings may also compliment those of Shanahan et al. (2011) who found a possible role of irrational beliefs, relating to the world and others, in anger. Given the likely importance of anger in the development of violence, further research on the links between anger, negative self-referent interpretations and violence would clarify how interventions that target irrational beliefs and the prevention of anger arousal may also be indicated.

Conclusions

The findings of this study are consistent with the cognitive model of violence with offenders and aggressive control participants interpreting interpersonal situations in a negative manner. The findings also raise further questions about the factors that mediate the relationship between negative interpretations of interpersonal situations and serious violent offending.

Executive summary

A test of a cognitive model of violence: a comparison of thinking in violent and non-violent men.

Emily Garner, Department of Psychology, University of Bath
June 2015

Word count: 1022
There has been considerable research into the factors that might lead to a person being violent. These include factors that don’t change (‘static’ risk factors) such as gender or previous violent offending. These exist alongside factors that might change (‘dynamic’ risk factors) such as how much alcohol a person drinks, and environmental factors such as the other people who are around at the time. In addition, there have been studies looking at the psychological factors that might contribute to violence, for example how angry an individual is.

Recently some researchers pulled together evidence from different studies and their own experiences in working with violent offenders and developed a framework (the cognitive model of violence) for thinking about how and why a person becomes violent. This framework suggests that people who have grown up in a violent, abusive or neglectful environment might start to believe that this is because there is something bad about them – or that they are weak or vulnerable for feeling frightened. Without necessarily knowing it, these people might then develop ‘rules’ to help hide these things about themselves from other people. For example, someone might have the rule ‘I must never show others that I am vulnerable’, or ‘fear is a sign of weakness so I must not let other people see that I am scared, I must show that I am strong instead.’ The framework then suggests that something might happen (a ‘trigger’, which is interpreted as a deliberate action on the part of another person) which either makes the person feel embarrassed or makes them think that they might feel embarrassed, and hence vulnerable. Embarrassment and humiliation are unpleasant feelings and are linked to anxiety and fear. So if a person who really wants not to show these feelings suddenly experiences embarrassment, their rules might come into play and they might try to show that they are strong by fighting and ‘getting the better’ of the person who they consider has humiliated them or shown them to be vulnerable. This resulting violent behaviour might make them feel better in the short-term, but in the long-run it serves to strengthen their beliefs: that they are weak or vulnerable and need to keep sticking to their rules to make sure that other people don’t see this or otherwise take advantage of them.

The reason for doing this research study was to test whether this framework reflects the processes involved in violence in reality. A small part of the framework relating to how a person interprets social situations was looked at in detail. The framework suggests that people who are violent will have an enduring tendency to misinterpret the ambiguous actions of other people as humiliating or disrespectful to a greater extent than people who are not violent. A questionnaire, the Violence Interpretation Questionnaire (VIQ), was therefore developed to test this theory. The questionnaire was given to participants to complete, along with some other measures – one about violent thinking, one about how people feel about themselves and one asking about incidences of violent behaviour in the past year. Three groups of participants completed the study: an ‘offender group’ of 17 violent offenders from the probation service and a sample of online control participants who were split into two groups depending on how they
responded to the questionnaire about violent behaviour, giving an aggressive control group of 28 participants and a non-aggressive control group of 69. The offender group also completed a questionnaire to give the researcher an idea about how accurate their responses were. (It can understandably be difficult to be completely honest when talking to a researcher, especially when talking about things that are against the law. This measure was included to give an idea of how reliable the responses of offenders were.)

The results of the study found that, as predicted by the theory, the offender group and the aggressive control group both made more negative interpretations of social situations than the non-aggressive control group. Also as expected, there was no difference between the groups’ appraisals of non-social situations, which suggests that the negative interpretations were specific only to situations with other people. Participants were also asked what they would do in these social situations. Surprisingly, although the aggressive control and offender groups interpreted the situations in the same way, the aggressive control group said that they would behave in the same way as non-aggressive controls – less aggressively than the offenders. There was also a link between violent thinking on a different measure (the Maudsley Violence Questionnaire) and scores on the VIQ that suggests that the latter is picking up the information that it is designed to do.

The findings of this study are interesting. They provide some evidence that the framework for thinking about how violence develops is accurate. The study also highlighted something new; the aggressive control group interpreted social situations in the same way as the offender group but predicted that, like the non-aggressive control group, they would respond less aggressively than the offenders. This suggests that there might be another important factor involved in violence; there is something that means that the offenders interpret social situations negatively and are more likely to go on to be violent, whereas the aggressive controls interpret this way but are less likely to behave in a violent manner. Some ideas for this difference were suggested. For example, the offenders may be more impulsive and so less able to stop themselves reacting physically than the aggressive control group. Another suggestion is that the aggressive control group might be more aware and fearful of the consequences of being violent (such as getting hurt or into trouble). Alternatively, the aggressive control group might care less about what others think about them than the offenders and so feel less need to attack or retaliate or attack to show their strength.

However, these are just hypotheses and more research needs to be done. Another study with more people would make the results more convincing. It would also be interesting to conduct a study with people who would fit in the aggressive control group to find out what stops them from committing violent offences.
Narrative overview

Emily Garner, Department of Psychology, University of Bath

June 2015

Word count: 2329
Clinical psychology training has provided the opportunity to develop my research skills and to learn about combining research and clinical practice. My three research projects have been very different in terms of design and implementation but have a common theme of a cognitive-behavioural approach. Alongside my research skills I also feel that these projects have helped me to develop my understanding of cognitive frameworks and treatments.

**Critical review of the literature**

I systematically reviewed psychological interventions for bipolar disorder and the differential effect of such interventions upon depression and mania. Although a full range of psychological approaches were included in the searches the exclusion criteria resulted in exploration of only two in depth; psychoeducation and CBT. This was mainly because studies of other approaches used out-dated screening tools or did not report a follow-up period.

The focus of the review was developed in collaboration with my supervisor, Dr James Gregory, who had a prior research interest in the field. Consideration was given to recent narrative reviews of the psychological treatment of bipolar disorder that made brief reference to differential effects on depression and mania, but whose design and methodology were flawed. It was agreed that there was justification for a review specifically on this topic. It was also decided that a systematic review would be conducted in order to provide a more methodologically robust account of the evidence than those already published. I have been pleased with this decision and have come to recognise both the value of, and the substantial amount of work involved in, conducting such a review.

High-quality systematic reviews include quality analysis and inter-ratings for the screening process and data extraction. We were presented with a challenge; how to fulfil these aspects, thus ensuring that the review would be methodologically sound, whilst also being realistic in respect to the time constraints of clinical training. A solution was found through approaching two other trainee clinical psychologists who had decided to conduct systematic reviews. It was agreed that we would act as inter-raters for each other, allowing us each to demonstrate the rigour necessary for a high-quality review. It was further agreed that rather than inter-rating the entire screening process a proportion of papers (selected at random) would be screened to make the process broadly equitable across the three reviews, which worked very well.

Writing the results section of the review was particularly challenging. At times I felt overwhelmed by the variety of outcome variables across studies and the difficulties I found in integrating them into a coherent, meaningful synthesis. After the synthesis was carried out it became clear that results were inconsistent across approaches with some finding good effects for depression and others for mania. The review showed that the literature is inconsistent and requires further attention; a valuable addition to the research evidence of bipolar disorder. In
writing the review I was surprised that the majority of interventions were not based upon disorder-specific theoretical models similarly to those upon which successful treatments of anxiety disorders are based. Given the serious nature of bipolar disorder and the high suicide rate of individuals with this diagnosis it seemed surprising that more emphasis had not been placed in gaining an accurate understanding of the mechanisms of the disorder. I am therefore pleased that my review has been able to highlight this important gap in the literature and hope that it will make a meaningful difference to those with bipolar disorder, despite the inconclusive findings.

**Service improvement project**

My service improvement project was conducted in a local secondary care mental health service and was supervised by Dr Chris Gillmore and Dr Claire Lomax. Chris attended the first year research fair with an initial idea of evaluating a transdiagnostic group CBT intervention. In collaboration with Claire, we designed the project and particularly considered the service improvement aspect of the project; we agreed that out of the evaluation I would make recommendations in reference to available literature on this topic and conduct a re-evaluation after these had been implemented.

The introduction of the project allowed me to review transdiagnostic CBT interventions; an area not covered in our teaching. It was interesting to develop an understanding of this topic and the potential utility in providing treatment to large numbers of people. It also highlighted to me the common processes that underpin different mental health difficulties, particularly anxiety disorders.

The project presented various challenges which included coming into a service as an external professional and evaluating an intervention that was developed and implemented by members of the team. There was the potential for this to be a threatening process for the team and consideration was given to framing the project accurately; as a means of improving effectiveness for patients, rather than an assessment of the skills of the team. The findings of the initial evaluation were very positive and highlighted good effects of the treatment. This feedback was given at a team meeting and prompted an interesting discussion about some of the limitations of the evaluation and acknowledgment that this innovative intervention should be shared across the Trust and the wider field. I have submitted an article to the Cognitive Behaviour Therapist journal in order to disseminate more broadly.

Following the evaluation I made a number of recommendations for the team to implement in order to collect more robust information to inform future effectiveness studies. The initial evaluation was limited due to a lack of information relating to demographics, diagnoses and session-by-session ratings. Understandably, many of the recommendations were not implemented due to the time demands (i.e. the use of a diagnostic screening tool) and those that were employed were done so in an inconsistent manner. For example, due to
miscommunication, session-by-session feedback was not obtained with only around half of sessions being evaluated in this way. I realised that many of the recommendations related to demonstrating the positive outcomes of the group in a more robust manner but this was understandably not a priority of the team. I found this a little frustrating as I felt there was potential to evidence an important treatment approach for stretched mental health services. However, whilst recognising that the service is not in the position to prioritise high-quality research methodologies at present, I am hopeful that, if accepted for publication, the article about the initial evaluation will accomplish this aim and publicly celebrate the achievements of the team.

**Main research paper**

I have held an interest in forensic psychology since my undergraduate lectures on the topic and subsequent post as an assistant psychologist in a forensic inpatient unit. When the time came to develop research ideas I met with a colleague from this setting, Dr Julian Walker, to discuss potential ideas. Julian had published a number of articles relating to violence and the role of self-esteem and humiliation in violent behaviour. He had developed a cognitive framework for thinking about violence and suggested the validation of this model in some way might form an interesting and valuable project. Prof Paul Salkovskis has been my academic supervisor and his knowledge of testing out proposed theoretical models led to several ideas and the eventual borrowing of a methodology previously employed to test the cognitive model of panic disorder.

The development of the Violence Interpretation Questionnaire (VIQ) was lengthy. Various formats were suggested and the final one was decided upon after piloting it with friends. Generating ambiguous social situations was difficult but more so were the non-social control items. It was interesting how difficult it was to think of situations that might threaten one’s self-esteem that do not involve interactions with other people.

Obtaining ethical approval from the National Offender Management Service was difficult. Unfortunately the forms were submitted over the summer meaning that many people were on leave and it took a considerable amount of time to get initial feedback that provided conditional approval subject to a number of modifications. These included not providing a financial incentive to participants, which felt like a significant setback at the time as I imagined that without this few would agree to participate.

Once approval was obtained there were some further delays in starting recruitment due to redesign of probation services and a considerable amount of uncertainty in the department in which I was intending to recruit. In December of my final year things were more conducive to recruitment and Julian and I approached managers and some key probation officers in the team who seemed positive about the project. However, despite numerous emails, phone calls and meetings, probation officers did not initially respond to my requests for assistance in identifying
and approaching participants about the study. In the new year, with obvious time pressures, I began to spend as much time as possible in the probation offices. I found that talking to people individually and face-to-face was really important in helping them to feel invested in the project and building relationships with probation officers helped them to keep me and my requests in mind. There seemed to be two main factors that limited recruitment. Firstly, a large proportion of the IRIS caseload had convictions of sexual offences and, secondly, due to the high-risk nature of the offenders, many were recalled to prison during the study period. It was therefore necessary to extend recruitment of the offender sample to general probation rather than solely high-risk offenders from IRIS.

Once approval for this amendment was obtained I began to approach other probation officers and managers of approved probation premises in the region. However, without direct face-to-face contact I did not receive positive responses. Some were dismissive of the study stating their lack of time and others were somewhat suspicious of me and my role. The key to finding individuals, therefore, appeared to be meeting individually with probation officers and I spent increasing amounts of time at the police station talking to as many probation officers as I could find.

At the same time I tried to recruit a sample of 20 non-violent offenders from the IMPACT service who manage prolific offenders. When the proposal was written the feedback from members of the team indicated that there would be a large number of offenders who would fit the inclusion criteria. However, after attending a team meeting and presenting the details of the study to over 25 probation officers I received details of just two potential participants. I regularly met and communicated with the manager of the team and we adjusted the inclusion criteria of the non-violent offender sample to include Public Order Act offences that had originally constituted an exclusion criterion. Unfortunately this made no difference and in discussion with Julian and Paul we decided that we would not pursue this sample and would instead use a normative online sample as the control group.

This amendment, although necessary, was disappointing and I felt a little deflated that the study would be less valid. However, I have come to realise that the nature of research, particularly in the context of limited time, often leads to compromises but the results can nevertheless provide important additions to the literature.

Case studies

The case studies that I have completed on each of my placements have been helpful in a number of ways. I feel I have been able to think through specific cases clearly and logically through writing up the process of assessment and intervention, which I think has enhanced the intervention I have delivered to the individuals, involved and also has helped to develop my knowledge of the evidence-base and research skills.
Choosing appropriate cases to write-up has been a challenge throughout training and particularly when trying to use experimental designs. Using pre- and post-outcome measures has been generally manageable on all placements and I have tried to do this as a matter of course in my clinical work. However, to produce a case study with an experimental design a baseline of at least two, preferably three, data points prior to intervention was necessary. This proved more difficult to do and to ask individuals to complete outcome measures as many as three times before beginning any kind of intervention at times felt uncomfortable. This was perhaps exacerbated by the fact that the individual might not know the rationale for doing so as to broach the subject of consent to the case being written-up seemed premature. Despite this I found that the case studies really highlighted the importance of collecting a minimum of pre- and post-outcome data and ideally session-by-session outcome monitoring, and it was especially useful to have this rationale when working with some supervisors who did not use outcome measures routinely.

I found that knowing I needed to write at least one case study on each placement encouraged me to consider my assessments and interventions carefully. It was helpful to think about justifying a particular decision or course of treatment in text and this ensured that my interventions were based upon sound research evidence and NICE guidance where possible. It was also interesting to think about gaps in the literature and guidance, for example in the delivery of the ‘Finding a Way’ group for couples who were adjusting to a recent diagnosis of dementia.

Case studies can be important additions to the literature around particular problems or interventions. I think that writing up examples of clinical work is a realistic and manageable way in which clinical psychologists can continue to use their research knowledge and skills in NHS services where conducting research projects independently is extremely difficult due to limited time and resources.

Conclusions

The research component of the course has taught me a great deal and has helped to prepare me for the inevitable obstacles and barriers that I will face when conducting research in the NHS. At times I could understand why clinical psychologists often do not continue with research once qualified, with the challenges along the way sometimes feeling overwhelming. However, training has also emphasised the importance of evidence-based practice and I fully intend to continue adding to the research literature once qualified.
Acknowledgements

I would like to express my sincere thanks to my main research supervisors, Professor Paul Salkovskis and Dr Julian Walker for their guidance and support. Thanks also to Dr James Gregory, Dr Claire Lomax, Dr Chris Gillmore and Dr Megan Wilkinson-Tough for supervision, support and feedback on my literature review and service improvement project. I also want to thank my clinical tutor, Josie Millar.

I am hugely grateful to the staff in the probation service, who helped me to recruit participants, and to the participants themselves who gave up their time so generously.

I thank my fellow trainees Robbie Chandler, Rosie Chapman, Kate Cooper, Felicity Cowdrey, Siân Dallimore, Ania Grozdziej, Caroline Harvey, Charlotte Hazeldine, Vera Hughes, Sinéad Lambe, Row Pagdin, Sarah Rusbridge, Sasha Walters and Flora Wilson for their support and good humour.

Finally, special thanks to my family and partner for their continued encouragement and support throughout this journey.

</table>

**Note:** White background indicates a significant positive finding; light grey indicates no data reported for mania and depression separately; dark grey indicates no significant difference between treatment and control. CT has been included together with CBT interventions.

**Measures:** BDI = Beck Depression Inventory (Beck et al., 1996), BRMAS = Bech-Rafaelsen Mania Rating Scale (Bech et al., 1978), BRMS = Bech-Rafaelsen Melancholia Scale (Bech & Rafaelsen, 1980), HDRS = Hamilton Depression Rating Scale (Hamilton, 1960), MADRS = Montgomery-Asberg Depression Rating Scale (Snaith et al., 1986), SRMI = Self-Rating Mania Inventory (Shugar, Schertzer, Toner, & Di Gasbarro, 1992), YMRS = Young Mania Rating Scale (Young et al., 1978)

*Zaretsky et al. (2008) and Parikh et al. (2012) compared CBT and psychoeducation and are listed under CBT, however, results should be considered for psychoeducation also.

**Weiss et al. (2007) was the only study in which the intervention condition produced significantly worse results than control.*

Appendix G. Violence Interpretation Questionnaire (VIQ)

VIQ

Participant number: _______________  Date: _________

Below are some descriptions of situations in which it is not quite clear what is happening.

Please read each item in turn and answer the questions briefly. There are three parts to each item. Don’t think about it for too long – write down the first thing that comes into your mind.

1. Please write down what you think is happening and what you would do before turning over the page.

2. Turn over the page and arrange the possible explanations for the situation in order in which they would be most likely to come to your mind if you found yourself in a similar situation. This means that the one which you are most likely to think comes first and the one you are least likely to think comes third.

3. Then choose from the three options of things that you might do. Choose the one that you are most likely to do out of the options.

Don’t worry if none of the options fits exactly with what you think or what you would do.

There is a sample item to complete before the questionnaire items.
Sample item

a) You see a man running down the road carrying a woman’s handbag.

Why?

_________________________________________________________
_________________________________________________________
_________________________________________________________

What would you do?

_________________________________________________________
_________________________________________________________
_________________________________________________________

Sample item

b) You see a man running down the road carrying a woman’s handbag.

Please rank the following options in terms of the most likely explanation (using a scale of 1-3 (where 1 is most likely and 3 is least likely).

a) They are catching up with a woman who dropped her bag ______

b) They are carrying the bag for a friend ______

c) They have stolen the bag ______

What is the most likely thing you would you do in this situation? (Please tick one)

a) Carry on with what you were doing

b) Chase the man

c) Call the police
1.  a) You are in the pub with your friends. You notice that your friend is flirting with your partner.

Why?

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

What would you do?

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________
1. b) You are in the pub with your friends. You notice that your friend is flirting with your partner.

Please rank the following options in terms of the most likely explanation (using a scale of 1-3 (where 1 is most likely and 3 is least likely).

a) They are being friendly but harmless _____

b) They get a bit over the top when they've had a few drinks _____

c) They are trying to steal your partner _____

What is the most likely thing you would you do in this situation? (Please tick one)

a) Leave the pub with your partner

b) Have a conversation about it with your friend

c) Punch him
2. a) You cut yourself whilst shaving.

Why?

2. b) You cut yourself whilst shaving.

Please rank the following options in terms of the most likely explanation (using a scale of 1-3 (where 1 is most likely and 3 is least likely).

a) You weren’t paying enough attention _____

b) You are clumsy _____

c) The razor was blunt _____

What is the most likely thing you would do in this situation? (Please tick one)

a) Carry on shaving

b) Clean the cut

c) Throw the razor across the room and give up
3. a) You are making breakfast and you burn some toast.

Why?

What would you do?
3. b) You are making breakfast and you burn some toast

Please rank the following options in terms of the most likely explanation (using a scale of 1-3 (where 1 is most likely and 3 is least likely)).

a) You are useless _____

b) The toaster setting was accidentally turned up _____

c) You were distracted _____

What is the most likely thing you would do in this situation? (Please tick one)

a) Start again

b) Give up on breakfast

c) Smash the toaster on the floor
4. a) You are watching a film. You suddenly feel tearful.

Why?

What would you do?
4. b) You are watching a film. You suddenly feel tearful.

Please rank the following options in terms of the most likely explanation (using a scale of 1-3 (where 1 is most likely and 3 is least likely).

a) You are weak and pathetic _____
b) Sometimes things remind you of sad events in your life _____
c) The film is very sad _____

What is the most likely thing you would do in this situation? (Please tick one)

a) Turn the film off
b) Keep watching, it’s ok to feel emotional
c) Keep watching and make sure you don’t cry
5. a) You are walking through a park when you are hit on the back by a football.

Why?

Appendix I. SRVS

On the basis that it does not constitute a violent illegal act, item eight (highlighted in red) was removed from analysis prior to the control group being split into aggressive and non-aggressive groups.

Self Report Scale - F

ID number:

Instructions: Below is a list of things that people might do. Most people do lots of different activities and might break some rules from time to time. We want to get an idea of the things that you may have done. Please read these questions carefully and think about the things that you have done in the past 12 months.

Place a tick in the column that best tells how often you have done these things.

| Have you in the past 12 months: | Never 1-3 4-6 Once a More than |
|-------------------------------|-------|-------|-------|-----|
|                               | times | times | month | once a month |

1. Purposely hurt or beaten up someone?

2. Taken part in a fist fight in which a group of people was against another group

3. Used a weapon of some sort e.g. knife, stick, chains, or a bottle in a fight

4. Used or threatened to use force to get money or things from another person?

5. Taken part in an armed robbery or forcing someone to do something with a weapon?

6. Hit, pushed, punched or slapped someone else?

7. Harmed or been cruel to an animal or pet?

8. Been involved in bullying another person?

9. Carried a weapon (e.g. a knife, gun) for self-defence or to use against someone?
Appendix J. Participant information sheet

A test of a cognitive model of violence: a comparison of thinking of violent and non-violent men

Information Sheet

We are inviting you to take part in a research study looking at how peoples’ thinking affects their violent behaviour.

Before you decide whether or not to take part, it is important for you to understand why the research is being done and what it will involve.

If you decide that you would like to take part, or if you have any further questions, your probation officer will let a researcher know and they will get in touch with you to arrange a convenient time to meet you at Bridewell Police Station. If you would like to take part in the research you be asked to sign a consent form and you will be given a copy.

Thank you for reading this and for your interest in the research.

What is the study about?
There has been a lot of research in the past into the causes of violence. This study is looking at how people’s thinking about different situations can contribute to violent behaviour. It is hoped that this may help us to find better ways to help people who have difficulties controlling aggression.

Why have I been chosen?
We are asking about 60 people to take part in the study. Half of these people have a history of violent offending and half do not, but all are in contact with the South West and South Central division of the National Probation Service or the Bristol, Gloucestershire, Somerset and Wiltshire Community Rehabilitation Company. You are being asked because you are under the care of one of these services.

Do I have to take part?
No – you only take part if you want to. If you decide to take part you can withdraw at any time and you don’t have to give a reason. If you don’t want to take part, or if you decide to stop and withdraw, this won’t affect the care you get or you progress through the system.

What do I have to do?
If you do decide to take part, a researcher will contact you in person and arrange a time to meet you at Bridewell police station. You will be asked for some background information and will then be asked to complete five questionnaires. Two of the questionnaires are about your thoughts and feelings about violence. One questionnaire is about how you think and feel about yourself. There is a questionnaire about any violence you have been involved with in the last year and one asks questions that check the validity of responses. The
questionnaires will be fully explained to you before you complete them and a researcher will be available to help you.

Taking part in the study should take no longer than 60 minutes.

We will also ask your permission to look at your probation records and information about any history of violence you may have will be recorded. This will be completely anonymous – no information will be recorded that could identify you in any way.

**Will my taking part in this study be kept confidential?**

None of your answers will be shared with Probation staff. All of the information that you give us will be anonymous and confidential. The only exception is if you say something that makes us concerned about your or someone else’s safety or if you disclose a serious offence not yet known to the police. In this case that information – and only that information – would be shared with Probation staff.

**What will happen to the results of the research study?**

The results of the study will be written up into a report and will also eventually be published in an academic journal, as well as possibly being used in academic presentations. All results will be shown as group results – no individual results will be used so it will be impossible to identify you from the publication.

**What are the disadvantages or risks of taking part?**

Other than taking an hour of your time we don’t think there are any disadvantages to taking part. But if you are worried about anything, please ask. If you feel distressed or anxious for any reason after participating in the study, please talk to the researcher or your Probation Officer who will be able to direct you to voluntary or NHS services for support as necessary.

**What are the benefits of taking part?**

You will be taking part in an important research study that may help to develop better ways of supporting people who are violent. Reasonable travel expenses will be covered. If you would like to see the results of the study please let the researcher know.

**Who is organising and funding the research?**

The University of Bath is funding the research in collaboration with the National Probation Service.

**Who has reviewed the study?**

This research has been reviewed and approved by the University of Bath Ethics Committee and by the National Offender Management Service.

If you would like more information about the project, please contact your Probation Officer who can pass your query to the research team.
Appendix K. Participant consent form

A test of a cognitive model of violence: a comparison of thinking of violent and non-violent men

Consent Form

Please tick box

1. I confirm that I have read and understand the information sheet for the above study and have had the opportunity to ask questions.

2. I understand that my participation is voluntary and that I am free to withdraw at any time, without giving any reason, without my medical care, progress or legal rights being affected.

3. I understand that the information I provide will remain secure and confidential and will be held no longer than necessary for the purposes of this research.

4. I agree to take part in the above study.

5. I understand that sections of my probation record may be looked at by members of the research team where it is relevant to my taking part in the research. I give my permission for these individuals to have access to my records.

6. I agree that a copy of this consent form can go into my probation record.

Name of participant  Date  Signature

Contact details: _____________________________________________________________

1 copy for participant; 1 copy for researcher; 1 copy to be kept in probation records

PLEASE KEEP YOUR COPY OF THE INFORMATION SHEET AND CONSENT FORM

Appendix N. Paulhus Deception Scales (PDS) scores

The PDS was administered to the offender group due to the increased likelihood of socially desirable responding in the sample. The mean score on the IM subscale of 7.01 (SD=3.36) is below the threshold that indicates results may be invalid, however eight of the 17 participants did exceed this level. This highlights a tendency for socially desirable responding in some participants in the offender group. Furthermore, there was a significant negative correlation between IM score and MVQ acceptance score in the offender group ($r=-0.72, n=17, p<0.01$) showing that participants who responded in a socially desirable manner on the PDS were likely to respond similarly on the MVQ (i.e. minimising their acceptance of ‘normal’ violence and aggression).
Appendix O. *Clinical Psychology Review* author guidelines

**TABLE OF CONTENTS**

- Description ........................................ p.1
- Audience .......................................... p.1
- Impact Factor ...................................... p.1
- Abstracting and Indexing ....................... p.2
- Editorial Board .................................. p.2
- Guide for Authors ................................ p.3

**DESCRIPTION**

*Clinical Psychology Review* publishes substantive reviews of topics germane to *clinical psychology*. Papers cover diverse issues including: psychopathology, psychotherapy, behavior therapy, cognition and cognitive therapies, behavioral medicine, community mental health, assessment, and child development. Papers should be cutting edge and advance the science and/or practice of clinical psychology.

Reviews on other topics, such as psychophysiology, learning therapy, experimental psychopathology, and social psychology often appear if they have a clear relationship to research or practice in *clinical psychology*. Integrative literature reviews and summary reports of innovative ongoing clinical research programs are also sometimes published. Reports on individual research studies and theoretical treatises or clinical guides without an empirical base are not appropriate.

**Benefits to authors**

We also provide many author benefits, such as free PDFs, a liberal copyright policy, special discounts on Elsevier publications and much more. Please click here for more information on our author services.

Please see our Guide for Authors for information on article submission. If you require any further information or help, please visit our support pages: http://support.elsevier.com

GUIDE FOR AUTHORS

BEFORE YOU BEGIN

Ethics in publishing
For information on Ethics in publishing and Ethical guidelines for journal publication see http://www.elsevier.com/publishingethics and http://www.elsevier.com/journal-authors/ethics.

Conflict of interest
All authors are requested to disclose any actual or potential conflict of interest including any financial, personal or other relationships with other people or organizations within three years of beginning the submitted work that could inappropriately influence, or be perceived to influence, their work. See also http://www.elsevier.com/conflictsofinterest. Further information and an example of a Conflict of Interest form can be found at: http://help.elsevier.com/app/answers/detail/a_id/286/p/7923.

Submission declaration and verification
Submission of an article implies that the work described has not been published previously (except in the form of an abstract or as part of a published lecture or academic thesis or as an electronic preprint, see http://www.elsevier.com/sharingpolicy), that it is not under consideration for publication elsewhere, that its publication is approved by all authors and tacitly or explicitly by the responsible authorities where the work was carried out, and that, if accepted, it will not be published elsewhere in the same form, in English or in any other language, including electronically without the written consent of the copyright-holder. To verify originality, your article may be checked by the originality detection service CrossCheck http://www.elsevier.com/editors/plagdetect.

Changes to authorship
This policy concerns the addition, deletion, or rearrangement of author names in the authorship of accepted manuscripts:
Before the accepted manuscript is published in an online issue: Requests to add or remove an author, or to rearrange the author names, must be sent to the Journal Manager from the corresponding author of the accepted manuscript and must include: (a) the reason the name should be added or removed, or the author names rearranged and (b) written confirmation (e-mail, fax, letter) from all authors that they agree with the addition, removal or rearrangement. In the case of addition or removal of authors, this includes confirmation from the author being added or removed. Requests that are not sent by the corresponding author will be forwarded by the Journal Manager to the corresponding author, who must follow the procedure as described above. Note that: (1) Journal Managers will inform the Journal Editors of any such requests and (2) publication of the accepted manuscript in an online issue is suspended until authorship has been agreed.
After the accepted manuscript is published in an online issue: Any requests to add, delete, or rearrange author names in an article published in an online issue will follow the same policies as noted above and result in a corrigendum.

Author Disclosure Policy
Authors must provide three mandatory and one optional author disclosure statements. These statements should be submitted as one separate document and not included as part of the manuscript. Author disclosures will be automatically incorporated into the PDF builder of the online submission system. They will appear in the journal article if the manuscript is accepted.

The four statements of the author disclosure document are described below. Statements should not be numbered. Headings (i.e., Role of Funding Sources, Contributors, Conflict of Interest, Acknowledgements) should be in bold with no white space between the heading and the text. Font size should be the same as that used for references.

Statement 1: Role of Funding Sources
Authors must identify who provided financial support for the conduct of the research and/or preparation of the manuscript and to briefly describe the role (if any) of the funding sponsor in study design, collection, analysis, or interpretation of data, writing the manuscript, and the decision to submit the manuscript for publication. If the funding source had no such involvement, the authors should so state.
Example: Funding for this study was provided by NIAAA Grant R01-AA123456. NIAAA had no role in the study design, collection, analysis or interpretation of the data, writing the manuscript, or the decision to submit the paper for publication.

Statement 2: Contributors
Authors must declare their individual contributions to the manuscript. All authors must have materially participated in the research and/or the manuscript preparation. Roles for each author should be described. The disclosure must also clearly state and verify that all authors have approved the final manuscript.

Example: Authors A and B designed the study and wrote the protocol. Author C conducted literature searches and provided summaries of previous research studies. Author D conducted the statistical analysis. Author B wrote the first draft of the manuscript and all authors contributed to and have approved the final manuscript.

Statement 3: Conflict of Interest
All authors must disclose any actual or potential conflict of interest. Conflict of interest is defined as any financial or personal relationships with individuals or organizations, occurring within three (3) years of beginning the submitted work, which could inappropriately influence, or be perceived to have influenced the submitted research manuscript. Potential conflict of interest would include employment, consultancies, stock ownership (except personal investments equal to the lesser of one percent (1%) of total personal investments or USD$5000), honoraria, paid expert testimony, patent applications, registrations, and grants. If there are no conflicts of interest by any author, it should state that there are none.

Example: Author B is a paid consultant for XYZ pharmaceutical company. All other authors declare that they have no conflicts of interest.

Statement 4: Acknowledgements (optional)
Authors may provide Acknowledgements which will be published in a separate section along with the manuscript. If there are no Acknowledgements, there should be no heading or acknowledgement statement.

Example: The authors wish to thank Ms. A who assisted in the proof-reading of the manuscript.

Copyright
Upon acceptance of an article, authors will be asked to complete a ‘Journal Publishing Agreement’ (for more information on this and copyright, see http://www.elsevier.com/copyright). An e-mail will be sent to the corresponding author confirming receipt of the manuscript together with a ‘Journal Publishing Agreement’ form or a link to the online version of this agreement.

Subscribers may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions. Permission of the Publisher is required for resale or distribution outside the institution and for all other derivative works, including compilations and translations (please consult http://www.elsevier.com/permissions). If excerpts from other copyrighted works are included, the author(s) must obtain written permission from the copyright owners and credit the source(s) in the article. Elsevier has preprinted forms for use by authors in these cases: please consult http://www.elsevier.com/permissions.

For open access articles: Upon acceptance of an article, authors will be asked to complete an ‘Exclusive License Agreement’ (for more information see http://www.elsevier.com/OAauthoragreement). Permitted third party reuse of open access articles is determined by the author’s choice of user license (see http://www.elsevier.com/openaccesslicenses).

Author rights
As an author you (or your employer or institution) have certain rights to reuse your work. For more information see http://www.elsevier.com/copyright.
Role of the funding source
You are requested to identify who provided financial support for the conduct of the research and/or preparation of the article and to briefly describe the role of the sponsor(s), if any, in study design; in the collection, analysis and interpretation of data; in the writing of the report; and in the decision to submit the article for publication. If the funding source(s) had no such involvement then this should be stated.

Funding body agreements and policies
Elsevier has established a number of agreements with funding bodies which allow authors to comply with their funder's open access policies. Some authors may also be reimbursed for associated publication fees. To learn more about existing agreements please visit http://www.elsevier.com/fundingbodies.

Open access
This journal offers authors a choice in publishing their research:

Open access
• Articles are freely available to both subscribers and the wider public with permitted reuse
• An open access publication fee is payable by authors or on their behalf e.g. by their research funder or institution

Subscription
• Articles are made available to subscribers as well as developing countries and patient groups through our universal access programs (http://www.elsevier.com/access).
• No open access publication fee payable by authors.

Regardless of how you choose to publish your article, the journal will apply the same peer review criteria and acceptance standards.

For open access articles, permitted third party (re)use is defined by the following Creative Commons user licenses:

Creative Commons Attribution (CC BY)
Let others distribute and copy the article, create extracts, abstracts, and other revised versions, adaptations or derivative works of or from an article (such as a translation), include in a collective work (such as an anthology), text or data mine the article, even for commercial purposes, as long as they credit the author(s), do not represent the author as endorsing their adaptation of the article, and do not modify the article in such a way as to damage the author's honor or reputation.

Creative Commons Attribution-NonCommercial-NoDerivs (CC BY-NC-ND)
For non-commercial purposes, let others distribute and copy the article, and to include in a collective work (such as an anthology), as long as they credit the author(s) and provided they do not alter or modify the article.

The open access publication fee for this journal is USD 1800, excluding taxes. Learn more about Elsevier's pricing policy: http://www.elsevier.com/openaccesspricing.

Language (usage and editing services)
Please write your text in good English (American or British usage is accepted, but not a mixture of these). Authors who feel their English language manuscript may require editing to eliminate possible grammatical or spelling errors and to conform to correct scientific English may wish to use the English Language Editing service available from Elsevier’s WebShop (http://webshop.elsevier.com/languageediting/) or visit our customer support site (http://support.elsevier.com) for more information.

Submission
Our online submission system guides you stepwise through the process of entering your article details and uploading your files. The system converts your article files to a single PDF file used in the peer-review process. Editable files (e.g., Word, LaTeX) are required to typeset your article for final publication. All correspondence, including notification of the Editor's decision and requests for revision, is sent by e-mail.

PREPARATION
**Use of word processing software**

It is important that the file be saved in the native format of the word processor used. The text should be in single-column format. Keep the layout of the text as simple as possible. Most formatting codes will be removed and replaced on processing the article. In particular, do not use the word processor's options to justify text or to hyphenate words. However, do use bold face, italics, subscripts, superscripts etc. When preparing tables, if you are using a table grid, use only one grid for each individual table and not a grid for each row. If no grid is used, use tabs, not spaces, to align columns. The electronic text should be prepared in a way very similar to that of conventional manuscripts (see also the Guide to Publishing with Elsevier: http://www.elsevier.com/guidepublication). Note that source files of figures, tables and text graphics will be required whether or not you embed your figures in the text. See also the section on Electronic artwork.

To avoid unnecessary errors you are strongly advised to use the ‘spell-check’ and ‘grammar-check’ functions of your word processor.

**Article structure**

Manuscripts should be prepared according to the guidelines set forth in the Publication Manual of the American Psychological Association (6th ed., 2009). Of note, section headings should not be numbered.

Manuscripts should ordinarily not exceed 50 pages, including references and tabular material. Exceptions may be made with prior approval of the Editor in Chief. Manuscript length can often be managed through the judicious use of appendices. In general the References section should be limited to citations actually discussed in the text. References to articles solely included in meta-analyses should be included in an appendix, which will appear in the on line version of the paper but not in the print copy. Similarly, extensive Tables describing study characteristics, containing material published elsewhere, or presenting formulas and other technical material should also be included in an appendix. Authors can direct readers to the appendices in appropriate places in the text.

It is authors’ responsibility to ensure their reviews are comprehensive and as up to date as possible (at least through the prior calendar year) so the data are still current at the time of publication. Authors are referred to the PRISMA Guidelines (http://www.prisma-statement.org/statement.htm) for guidance in conducting reviews and preparing manuscripts. Adherence to the Guidelines is not required, but is recommended to enhance quality of submissions and impact of published papers on the field.

**Appendices**

If there is more than one appendix, they should be identified as A, B, etc. Formulae and equations in appendices should be given separate numbering: Eq. (A.1), Eq. (A.2), etc.; in a subsequent appendix, Eq. (B.1) and so on. Similarly for tables and figures: Table A.1; Fig. A.1, etc.

**Essential title page information**

**Title.** Concise and informative. Titles are often used in information-retrieval systems. Avoid abbreviations and formulae where possible. Note: The title page should be the first page of the manuscript document indicating the author’s names and affiliations and the corresponding author’s complete contact information.

**Author names and affiliations.** Where the family name may be ambiguous (e.g., a double name), please indicate this clearly. Present the authors’ affiliation addresses (where the actual work was done) below the names. Indicate all affiliations with a lower-case superscript letter immediately after the author’s name and in front of the appropriate address. Provide the full postal address of each affiliation, including the country name, and, if available, the e-mail address of each author within the cover letter.

**Corresponding author.** Clearly indicate who is willing to handle correspondence at all stages of refereeing and publication, also post-publication. Ensure that telephone and fax numbers (with country and area code) are provided in addition to the e-mail address and the complete postal address.
Present/permanent address. If an author has moved since the work described in the article was done, or was visiting at the time, a "Present address" (or "Permanent address") may be indicated as a footnote to that author's name. The address at which the author actually did the work must be retained as the main, affiliation address. Superscript Arabic numerals are used for such footnotes.

Abstract

A concise and factual abstract is required (not exceeding 200 words). This should be typed on a separate page following the title page. The abstract should state briefly the purpose of the research, the principal results and major conclusions. An abstract is often presented separate from the article, so it must be able to stand alone. References should therefore be avoided, but if essential, they must be cited in full, without reference to the reference list.

Graphical abstract

Although a graphical abstract is optional, its use is encouraged as it draws more attention to the online article. The graphical abstract should summarize the contents of the article in a concise, pictorial form designed to capture the attention of a wide readership. Graphical abstracts should be submitted as a separate file in the online submission system. Image size: Please provide an image with a minimum of 531 × 1328 pixels (h × w) or proportionally more. The image should be readable at a size of 5 × 13 cm using a regular screen resolution of 96 dpi. Preferred file types: TIFF, EPS, PDF or MS Office files. See http://www.elsevier.com/graphicalabstracts for examples.

Authors can make use of Elsevier’s Illustration and Enhancement service to ensure the best presentation of their images and in accordance with all technical requirements: Illustration Service.

Highlights

Highlights are mandatory for this journal. They consist of a short collection of bullet points that convey the core findings of the article and should be submitted in a separate editable file in the online submission system. Please use 'Highlights' in the file name and include 3 to 5 bullet points (maximum 85 characters, including spaces, per bullet point). See http://www.elsevier.com/highlights for examples.

Keywords

Immediately after the abstract, provide a maximum of 6 keywords, using American spelling and avoiding general and plural terms and multiple concepts (avoid, for example, 'and', 'of'). Be sparing with abbreviations: only abbreviations firmly established in the field may be eligible. These keywords will be used for indexing purposes.

Abbreviations

Define abbreviations that are not standard in this field in a footnote to be placed on the first page of the article. Such abbreviations that are unavoidable in the abstract must be defined at their first mention there, as well as in the footnote. Ensure consistency of abbreviations throughout the article.

Acknowledgements

Collate acknowledgements in a separate section at the end of the article before the references and do not, therefore, include them on the title page, as a footnote to the title or otherwise. List here those individuals who provided help during the research (e.g., providing language help, writing assistance or proof reading the article, etc.).

Footnotes

Footnotes should be used sparingly. Number them consecutively throughout the article. Many word processors can build footnotes into the text, and this feature may be used. Otherwise, please indicate the position of footnotes in the text and list the footnotes themselves separately at the end of the article. Do not include footnotes in the Reference list.

Electronic artwork

General points

• Make sure you use uniform lettering and sizing of your original artwork.
• Embed the used fonts if the application provides that option.
• Aim to use the following fonts in your illustrations: Arial, Courier, Times New Roman, Symbol, or use fonts that look similar.
• Number the illustrations according to their sequence in the text.
• Use a logical naming convention for your artwork files.
• Provide captions to illustrations separately.
• Size the illustrations close to the desired dimensions of the published version.
• Submit each illustration as a separate file.
A detailed guide on electronic artwork is available on our website:

You are urged to visit this site; some excerpts from the detailed information are given here.

Formats
If your electronic artwork is created in a Microsoft Office application (Word, PowerPoint, Excel) then
please supply ‘as is’ in the native document format.
Regardless of the application used other than Microsoft Office, when your electronic artwork is
finalized, please ‘Save as’ or convert the images to one of the following formats (note the resolution
requirements for line drawings, halftones, and line/halftone combinations given below):
EPS (or PDF): Vector drawings, embed all used fonts.
TIFF (or JPEG): Color or grayscale photographs (halftones), keep to a minimum of 300 dpi.
TIFF (or JPEG): Bитmapped (pure black & white pixels) line drawings, keep to a minimum of 1000 dpi.
TIFF (or JPEG): Combinations bitmapped line/halftone (color or grayscale), keep to a minimum of
500 dpi.

Please do not:
• Supply files that are optimized for screen use (e.g., GIF, BMP, PICT, WPG); these typically have a
  low number of pixels and limited set of colors;
• Supply files that are too low in resolution;
• Submit graphics that are disproportionately large for the content.

Color artwork
Please make sure that artwork files are in an acceptable format (TIFF (or JPEG), EPS (or PDF), or
MS Office files) and with the correct resolution. If, together with your accepted article, you submit
usable color figures then Elsevier will ensure, at no additional charge, that these figures will appear
in color online (e.g., ScienceDirect and other sites) regardless of whether or not these illustrations
are reproduced in color in the printed version. For color reproduction in print, you will receive
information regarding the costs from Elsevier after receipt of your accepted article. Please
indicate your preference for color: in print or online only. For further information on the preparation
of electronic artwork, please see http://www.elsevier.com/artworkinstructions.
Please note: Because of technical complications that can arise by converting color figures to ‘gray
scale’ (for the printed version should you not opt for color in print) please submit in addition usable
black and white versions of all the color illustrations.

Figure captions
Ensure that each illustration has a caption. Supply captions separately, not attached to the figure. A
caption should comprise a brief title (not on the figure itself) and a description of the illustration. Keep
text in the illustrations themselves to a minimum but explain all symbols and abbreviations used.

Tables
Please submit tables as editable text and not as images. Tables can be placed either next to the
relevant text in the article, or on separate page(s) at the end. Number tables consecutively in
accordance with their appearance in the text and place any table notes below the table body. Be
sparing in the use of tables and ensure that the data presented in them do not duplicate results
described elsewhere in the article. Please avoid using vertical rules.

References
Citations in the text should follow the referencing style used by the American Psychological
Association. You are referred to the Publication Manual of the American Psychological Association,
books.cfm?id=4200067 or APA Order Dept., P.O.B. 2710, Hyattsville, MD 20784, USA or APA, 3
Henrietta Street, London, WC3E BLU, UK. Details concerning this referencing style can also be found
at http://humanities.byu.edu/linguistics/Henrichsen/APA/APA01.html

Citation in text
Please ensure that every reference cited in the text is also present in the reference list (and vice
versa). Any references cited in the abstract must be given in full. Unpublished results and personal
communications are not recommended in the reference list, but may be mentioned in the text. If these
references are included in the reference list they should follow the standard reference style of the
journal and should include a substitution of the publication date with either 'Unpublished results' or 'Personal communication'. Citation of a reference as 'in press' implies that the item has been accepted for publication.

Web references
As a minimum, the full URL should be given and the date when the reference was last accessed. Any further information, if known (DOI, author names, dates, reference to a source publication, etc.), should also be given. Web references can be listed separately (e.g., after the reference list) under a different heading if desired, or can be included in the reference list.

References in a special issue
Please ensure that the words 'this issue' are added to any references in the list (and any citations in the text) to other articles in the same Special Issue.

Reference management software
Most Elsevier journals have a standard template available in key reference management packages. This covers packages using the Citation Style Language, such as Mendeley (http://www.mendeley.com/features/reference-manager) and also others like EndNote (http://www.endnote.com/support/enstyles.asp) and Reference Manager (http://refman.com/support/rmstyles.asp). Using plug-ins to word processing packages which are available from the above sites, authors only need to select the appropriate journal template when preparing their article and the list of references and citations to these will be formatted according to the journal style as described in this Guide. The process of including templates in these packages is constantly ongoing. If the journal you are looking for does not have a template available yet, please see the list of sample references and citations provided in this Guide to help you format these according to the journal style.

If you manage your research with Mendeley Desktop, you can easily install the reference style for this journal by clicking the link below:
http://open.mendeley.com/use-citation-style/clinical-psychology-review
When preparing your manuscript, you will then be able to select this style using the Mendeley plug-ins for Microsoft Word or LibreOffice. For more information about the Citation Style Language, visit http://citationstyles.org.

Reference style
References should be arranged first alphabetically and then further sorted chronologically if necessary. More than one reference from the same author(s) in the same year must be identified by the letters "a", "b", "c", etc., placed after the year of publication. References should be formatted with a hanging indent (i.e., the first line of each reference is flush left while the subsequent lines are indented).

Video data
Elsevier accepts video material and animation sequences to support and enhance your scientific research. Authors who have video or animation files that they wish to submit with their article are strongly encouraged to include links to these within the body of the article. This can be done in the same way as a figure or table by referring to the video or animation content and noting in the body text where it should be placed. All submitted files should be properly labeled so that they directly relate to the video file's content. In order to ensure that your video or animation material is directly usable, please provide the files in one of our recommended file formats with a preferred maximum size of 150 MB. Video and animation files supplied will be published online in the electronic version of your article in Elsevier Web products, including ScienceDirect: http://www.sciencedirect.com. Please supply 'stills' with your files: you can choose any frame from the video or animation or...
make a separate image. These will be used instead of standard icons and will personalize the link to your video data. For more detailed instructions please visit our video instruction pages at http://www.elsevier.com/artworkinstructions. Note: since video and animation cannot be embedded in the print version of the journal, please provide text for both the electronic and the print version for the portions of the article that refer to this content.

AudioSlides
The journal encourages authors to create an AudioSlides presentation with their published article. AudioSlides are brief, webinar-style presentations that are shown next to the online article on ScienceDirect. This gives authors the opportunity to summarize their research in their own words and to help readers understand what the paper is about. More information and examples are available at http://www.elsevier.com/audioslides. Authors of this journal will automatically receive an invitation e-mail to create an AudioSlides presentation after acceptance of their paper.

Supplementary material
Elsevier accepts electronic supplementary material to support and enhance your scientific research. Supplementary files offer the author additional possibilities to publish supporting applications, high-resolution images, background datasets, sound clips and more. Supplementary files supplied will be published online alongside the electronic version of your article in Elsevier Web products, including ScienceDirect: http://www.sciencedirect.com. In order to ensure that your submitted material is directly usable, please provide the data in one of our recommended file formats. Authors should submit the material in electronic format together with the article and supply a concise and descriptive caption for each file. For more detailed instructions please visit our artwork instruction pages at http://www.elsevier.com/artworkinstructions.

3D neuroimaging
You can enrich your online articles by providing 3D neuroimaging data in NIfTI format. This will be visualized for readers using the interactive viewer embedded within your article, and will enable them to: browse through available neuroimaging datasets; zoom, rotate and pan the 3D brain reconstruction; cut through the volume; change opacity and color mapping; switch between 3D and 2D projected views; and download the data. The viewer supports both single (.nii) and dual (.hdr and .img) NIfTI file formats. Recommended size of a single uncompressed dataset is maximum 150 MB. Multiple datasets can be submitted. Each dataset will have to be zipped and uploaded to the online submission system via the ‘3D neuroimaging data’ submission category. Please provide a short informative description for each dataset by filling in the ‘Description’ field when uploading a dataset. Note: all datasets will be available for downloading from the online article on ScienceDirect. If you have concerns about your data being downloadable, please provide a video instead. For more information see: http://www.elsevier.com/3DNeuroimaging.

Submission checklist
The following list will be useful during the final checking of an article prior to sending it to the journal for review. Please consult this Guide for Authors for further details of any item.

Ensure that the following items are present:
One author has been designated as the corresponding author with contact details:
• E-mail address
• Full postal address
All necessary files have been uploaded, and contain:
• Keywords
• All figure captions
• All tables (including title, description, footnotes)
Further considerations
• Manuscript has been ‘spell-checked’ and ‘grammar-checked’
• References are in the correct format for this journal
• All references mentioned in the Reference list are cited in the text, and vice versa
• Permission has been obtained for use of copyrighted material from other sources (including the Internet)
Printed version of figures (if applicable) in color or black-and-white
• Indicate clearly whether or not color or black-and-white in print is required.
• For reproduction in black-and-white, please supply black-and-white versions of the figures for printing purposes.
For any further information please visit our customer support site at http://support.elsevier.com.
AFTER ACCEPTANCE

Use of the Digital Object Identifier
The Digital Object Identifier (DOI) may be used to cite and link to electronic documents. The DOI consists of a unique alpha-numeric character string which is assigned to a document by the publisher upon the initial electronic publication. The assigned DOI never changes. Therefore, it is an ideal medium for citing a document, particularly 'Articles in press' because they have not yet received their full bibliographic information. Example of a correctly given DOI (in URL format; here an article in the journal Physics Letters B):
http://dx.doi.org/10.1016/j.physletb.2010.09.059
When you use a DOI to create links to documents on the web, the DOIs are guaranteed never to change.

Online proof correction
Corresponding authors will receive an e-mail with a link to our online proofing system, allowing annotation and correction of proofs online. The environment is similar to MS Word; in addition to editing text, you can also comment on figures/tables and answer questions from the Copy Editor. Web-based proofing provides a faster and less error-prone process by allowing you to directly type your corrections, eliminating the potential introduction of errors.
If preferred, you can still choose to annotate and upload your edits on the PDF version. All instructions for proofing will be given in the e-mail we send to authors, including alternative methods to the online version and PDF.
We will do everything possible to get your article published quickly and accurately. Please use this proof only for checking the typesetting, editing, completeness and correctness of the text, tables and figures. Significant changes to the article as accepted for publication will only be considered at this stage with permission from the Editor. It is important to ensure that all corrections are sent back to us in one communication. Please check carefully before replying, as inclusion of any subsequent corrections cannot be guaranteed. Proofreading is solely your responsibility.

Offprints
The corresponding author, at no cost, will be provided with a personalized link providing 50 days free access to the final published version of the article on ScienceDirect. This link can also be used for sharing via email and social networks. For an extra charge, paper offprints can be ordered via the offprint order form which is sent once the article is accepted for publication. Both corresponding and co-authors may order offprints at any time via Elsevier's WebShop (http://webshop.elsevier.com/myarticleservices/offprints). Authors requiring printed copies of multiple articles may use Elsevier WebShop's 'Create Your Own Book' service to collate multiple articles within a single cover (http://webshop.elsevier.com/myarticleservices/booklets).

AUTHOR INQUIRIES
You can track your submitted article at http://www.elsevier.com/track-submission. You can track your accepted article at http://www.elsevier.com/trackarticle. You are also welcome to contact Customer Support via http://support.elsevier.com.

Appendix P. *The Cognitive Behaviour Therapist* author guidelines

---

*The Cognitive Behaviour Therapist*

**Editor:**
Pamela Myles
Director of Training, Charlie Waller Institute of Evidence-Based Psychological Treatment, University of Reading

**Associate Editors:**
Allan Brownrigg, University of Northumbria
Vicki Curry, Islington Adolescent Outreach Team
Nick Grey, Centre for Anxiety Disorders and Trauma, Maudsley Hospital, London
Nick Hawkes, Barnet, Enfield and Haringey Mental Health NHS Trust
Allán Laville, University of Reading
Claire Lomax, Department of Psychology, University of Bath
Mark Papworth, University of Newcastle
Faramarz Hashempour, University of Bangor
Rachel Handley, University of Exeter
Natalie Taylor-Kerr, Isle of Man
Peter Langdon, University of East Anglia

**Aims and Scope**

*The Cognitive Behaviour Therapist* is an interdisciplinary peer reviewed journal aimed primarily at cognitive and behavioural practitioners in the helping and teaching professions. Published online, the journal features articles covering clinical and professional issues, which contribute to the theory, practice and evolution of the cognitive and behavioural therapies. The journal will publish papers that describe new developments; articles that are practice focussed and detail clinical interventions, research reports concerning the practice of cognitive behaviour therapy, detailed case reports, audits that are relevant to practice, and reviews of clinical scales and other assessment methods. The journal will also publish articles that have an education, training or supervision focus. It will also include reviews of recently published literature that is directly relevant to practitioners. A particular feature of the journal
is that its electronic nature is designed to ensure timeliness of publication and professional debate whilst also ensuring rigorous standards in the dissemination of high quality materials with relevance to the practice of the cognitive and behaviour therapies.

Editorial Governance

the Cognitive Behaviour Therapist encompasses most areas of human behaviour and experience, and represents many different research methods, from quantitative to qualitative research, how to do clinical interventions to detailed case studies.

Under the guidance of its editorial board the Cognitive Behaviour Therapist aims to reflect and influence the continuing changes in the concepts, methodology, and techniques within the cognitive and behaviour therapies.

BABCP

the Cognitive Behaviour Therapist is published for the British Association for Behavioural and Cognitive Psychotherapies and is the sister Journal to Behavioural and Cognitive Psychotherapy.

Editorial Statement – scope of journal content

The Editors welcome authoritative contributions from people working, or otherwise involved, in the practice, research, education, training and supervision in the cognitive and behaviour therapies. Articles must be original and focused upon cognitive and/or behaviour therapy. All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal. There is no formal word limit but concision is recommended.

The journal also welcomes additional or standalone multimedia materials that support, enhance or illustrate specific aspects of CBT or Education the submitted papers such as video or audio, power point presentations or transcripts of therapy sessions.

Practice Articles

The practice of the cognitive and behaviour therapies is based upon empirically grounded interventions. This section will explore this area by the publication of articles that describe
cognitive and behavioural interventions and the research evidence that underpins them or innovative interventions based on cognitive behavioural models. For new areas of application of CBT, articles providing an overview of CBT treatment issues could be considered, whereas in well-established areas, a more detailed approach to one or two specific aspects of therapy may be appropriate. All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal.

Reviews
Reviews of historical, contemporary, or innovative approaches to practice are also sought providing that they demonstrate relevance to the practice of the current of the cognitive and behavioural psychotherapies. Prospective authors for review papers should initially discuss their proposals with one of the editors.

Case Studies
Dissemination of effective practice will be promoted through the publication of case studies that involve cognitive and behavioural psychotherapy with individuals, couples, groups and families. A suggested template is provided which is designed to ensure sufficient information is provided to allow other therapists to replicate successful therapy. All articles must include 3-5 learning objectives that will be achieved through reading the article. At the end of each paper a summary of the main points should be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal. The case study should contribute to the development of theory or clinical practice, and feed into CBT practice as a whole rather than just relating to the specific case.

Authors may find the following guidelines for structure helpful:

- Abstract
- Learning objectives (3-5)
- Introduction: including an outline of theoretical research and clinical literature relevant to the case
• Presenting problem: including information on the presenting problem and associated
goals of treatment, diagnosis, relevant history and development of problems, scores
on standard and idiographic measures, relevant history
• Conceptualisation: including a relevant theory-based CBT model used as a framework
for formulation.
• Course of therapy: including methods used linked to theory and assessment of
progress; difficulties encountered and any innovations in therapy
• Outcome: including clinical change, progress towards goals, change to measures,
plans for follow-up
• Discussion: including relating to theory and evidence-base as well as reflections on
own practice; implications for therapy and recommendations for other clinicians
• Summary: main points of the paper including suggestions for follow-up reading

Original Research
Research evidence is at the heart of the practice of the cognitive and behavioural
psychotherapists. Original research will be published that is about and is directly relevant to
the practice of the cognitive and behaviour therapies, such as the therapeutic relationship,
therapeutic process and the evaluation of therapeutic strategies and techniques. It is expected
that such reports meet both the necessary standards of scientific rigour and the journal’s
requirement of clear implications for the practice of the cognitive and behavioural therapies.
Consequently, the description of the research and the presentation of results should be
sufficiently brief to enable sufficient discussion of the practice implications. Consideration
will be given to quantitative, qualitative and mixed approaches given appropriate fit between
the question, methodology and methods of research chosen. All articles must include a set of
3-5 learning objectives that will be achieved through reading the paper. At the end of each
paper a summary of the main points from the paper must be included with suggestions for
follow-up reading. This stipulation is in keeping with the practitioner and professional
development aims of the journal.

Education and Supervision
The dissemination of effective cognitive and behaviour therapy through evidence based
education and supervision strategies is important to ensure that service users receive
proficient therapy and therapists remain up to date. This section will explore educational
practice within the cognitive and behavioural psychotherapies. All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal.

Service Models and Forms of Delivery
The service model is the framework that exists to support the therapist with the delivery of either cognitive and behaviour therapies and services. This section will explore all aspects of the theory and application of service models and the delivery of therapy. Successes and failures have equal part to play in examining the practical application and the role of evidence within the provision of effective cognitive and behavioural interventions within a service context. Papers are invited which explore the structure of teams, processes adopted, the methods and designs involved. Papers that examine the outcomes of audits and their recommendations will also be considered. All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal.

Reviews of Assessment Tools and Methods
Reviews of clinical scales and other assessment methods will also be considered. These reviews should provide the practitioner with a review of a scale’s or other tool’s purpose and properties, sufficient information to know how and when to use it, and how to interpret the results and make use of them. All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal.

Submission of a manuscript
Papers should be submitted online at http://mc.manuscriptcentral.com/cbt
models, evaluations of innovative education strategies and approaches to the supervision of

**Style Guide**

- Title page. The title should phrase concisely the major issues. Author(s) to be given with departmental affiliations and addresses, grouped appropriately. A running head of no more than 40 characters should be indicated.
- Abstract. The abstract should include up to six key words that could be used to describe the article. This should summarize the article in no more than 250 words, references should not to be included in the abstract.
- All articles must include a set of 3-5 learning objectives that will be achieved through reading the paper. At the end of each paper a summary of the main points from the paper must be included with suggestions for follow-up reading. This stipulation is in keeping with the practitioner and professional development aims of the journal.
- Text. This should begin with an introduction, succinctly introducing the point of the paper to those interested in the general area of the journal. Attention should be paid to the Editorial Statement. References within the text should be given in the form of (Jones & Smith, 1973). When there are three or more authors the first citation should be given as Williams et al. (1973). The appropriate positions of tables and figures should be indicated in the text. Footnotes should be avoided where possible.
- References should be in the APA style. All citations in the text should be listed in strict alphabetical order according to surnames. Multiple references to the same author should be listed using a, b, etc., for entries within the same year. Note: Authors are encourages to include digital object identifiers (dois) in their citation listings, as follows:

- Declaration of interests should be included with all papers, if there are none this should be stated.
- Acknowledgements. May include previous unpublished presentations (e.g. dissertation, meeting paper), financial support, scholarly or technical assistance etc.
- Tables. Tables should be numbered and given explanatory titles.
- Figures:

Preferred formats
Required Statements
The four sections below must be included. These statements should be included in the front page, which should be uploaded separately to the main text of the article.

Acknowledgements
You may acknowledge individuals or organisations that provided advice, support (non-financial). Formal financial support and funding should be listed in the following section.

Financial Support
Please provide details of the sources of financial support for all authors, including grant numbers. For example, “This work was supported by the Medical research Council (grant number XXXXXXX).” Multiple grant numbers should be separated by a comma and space, and where research was funded by more than one agency the different agencies should be separated by a semi-colon, with “and before the final funder. Grants held by different authors should be identified as belonging to individual authors by the authors’ initials. For example, “This work was supported by the Wellcome Trust (A.B., grant numbers XXXX, YYYY), (C.D., grant number ZZZZ); the Natural Environment Research Council (E.F., grant number FFFF); and the National Institutes of Health (A.B., grant number GGGG), (E.F., grant number HHHH).

Where no specific funding has been provided for research, please provide the following statement: “This research received no specific grant from any funding agency, commercial or not-for-profit sectors.”

Conflict of Interest
Please provide details of all known financial, professional and personal relationships with the potential to bias the work. Where no known conflicts of interest exist, please include the following statement: “None.”

Ethical Standards
Where research involves human and/or animal experimentation, the following statements should be included (as applicable): “The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008.” and “The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional guides on the care and use of laboratory animals.”
• tif
• eps
• jpeg (acceptable for photographs / halftones)

Figure captions. Numbered captions should be typed on a separate page.

Please note that jpeg may not print well due to the compression process used which discards some data in the image. If you need to incorporate any text labels as part of the halftone then these will print jagged if the file is saved as a jpeg. Ideally you should import the halftone into illustration software for labeling and then save the file as an eps file. Gif formats are mainly suitable for online reproduction, and resolution is generally too low for print reproduction (only an issue when the article PDF is printed by a reader).

Resolution

All files must be a minimum of 300 dpi (dots per inch) for halftones, 600 dpi for combination figures and 1200 dpi for line art (black and white).

Colour

Colour files must be supplied as CMYK (not RGB) at a minimum resolution of 300 dpi. If an image is for a cover we may require a higher resolution. Note that the image size must be no smaller than the size at which it will appear in the journal.

Please do not submit your figures embedded into Word documents as the quality will be severely degraded.

If you require any further guidance on creating suitable electronic figures, please visit http://dx.sheridan.com/guidelines/digital_art.html. Here you will find extensive guidelines on preparing electronic figures and also have access to an online preflighting tool where you can check if your figures are suitable for reproduction.

Proofs, Reprints and Copyright

Proofs of accepted articles will be sent electronically to authors for the correction of printers’ errors; authors’ alterations may be charged. Authors submitting a manuscript do so on the understanding that if it is accepted for publication exclusive copyright of the paper shall be assigned to the Association. A PDF copy of the each paper will be supplied to the author.

Further reprints may be ordered at extra cost: the reprint order form will be sent with the proofs. The publishers will not put any limitation on the personal freedom of the author to use material contained in the paper in other works.
Author Language Services

Cambridge recommends that authors have their manuscripts checked by an English language native speaker before submission; this will ensure that submissions are judged at peer review exclusively on academic merit. We list a number of third-party services specialising in language editing and/or translation, and suggest that authors contact as appropriate. Use of any of these services is voluntary, and at the author's own expense.

DESCRIPTION

Personality and Individual Differences is devoted to the publication of articles (experimental, theoretical, review) which aim to integrate as far as possible the major factors of personality with empirical paradigms from experimental, physiological, animal, clinical, educational, criminological or industrial psychology or to seek an explanation for the causes and major determinants of individual differences in concepts derived from these disciplines. The editors are concerned with both genetic and environmental causes, and they are particularly interested in possible interaction effects. Ultimately they believe that human beings are bio-social organisms and that work on individual differences can be most fruitfully pursued by paying attention to both these aspects of our nature. They believe that advances are more likely to be made by the use of the hypothetical-deductive method, though empirical data based on sound research and providing interesting new findings, would of course not be rejected simply because they might not have a good theoretical underpinning. All in all, the traditional type of work on traits, abilities, attitudes, types and other latent structures underlying consistencies in behavior has in recent years been receiving rather short shrift in traditional journals of personality; Personality and Individual Differences aims to reinstate it to its proper place in psychology, equal in importance with general experimental work, and interacting with it to make up a unitary science of psychology.

Benefits to authors

We also provide many author benefits, such as free PDFs, a liberal copyright policy, special discounts on Elsevier publications and much more. Please click here for more information on our author services.

Please see our Guide for Authors for information on article submission. If you require any further information or help, please visit our support pages: http://support.elsevier.com

AUDIENCE

Social, experimental, educational, clinical and industrial psychologists.

GUIDE FOR AUTHORS

Your Paper Your Way

We now differentiate between the requirements for new and revised submissions. You may choose to submit your manuscript as a single Word or PDF file to be used in the refereeing process. Only when your paper is at the revision stage, will you be requested to put your paper in to a ‘correct format’ for acceptance and provide the items required for the publication of your article.

To find out more, please visit the Preparation section below.

INTRODUCTION

Neither the Editors nor the Publisher accept responsibility for the views or statements expressed by authors.

All incoming papers are subject to the refereeing process, unless they are not appropriate for the Aims and Scope of the journal as outlined, do not follow the Guide for Authors, or clearly suffer from methodological problems (e.g. unsatisfactory sample size). Correspondence regarding decisions reached by the editorial committee is not encouraged.

Click here to watch the recording of an author workshop presented by the Editor and Publisher of PAID. This video offers many practical tips for the preparation of your manuscript as well as useful background on the peer review and publication process.

BEFORE YOU BEGIN

Ethics in publishing

For information on Ethics in publishing and Ethical guidelines for journal publication see http://www.elsevier.com/publishingethics and http://www.elsevier.com/journal-authors/ethics.

Human and animal rights

If the work involves the use of animal or human subjects, the author should ensure that the work described has been carried out in accordance with The Code of Ethics of the World Medical Association (Declaration of Helsinki) for experiments involving humans http://www.wma.net/en/30publications/10policies/b3/index.html; EU Directive 2010/63/EU for animal experiments http://ec.europa.eu/environment/chemicals/lab_animals/legislation_en.htm; Uniform Requirements for manuscripts submitted to Biomedical journals http://www.icmje.org. Authors should include a statement in the manuscript that informed consent was obtained for experimentation with human subjects. The privacy rights of human subjects must always be observed.

Conflict of interest

All authors are requested to disclose any actual or potential conflict of interest including any financial, personal or other relationships with other people or organizations within three years of beginning the submitted work that could inappropriately influence, or be perceived to influence, their work. See also http://www.elsevier.com/conflictofinterest. Further information and an example of a Conflict of Interest form can be found at: http://help.elsevier.com/app/answers/detail/a_id/286/p/7923.

Submission declaration and verification

Submission of an article implies that the work described has not been published previously (except in the form of an abstract or as part of a published lecture or academic thesis or as an electronic preprint, see http://www.elsevier.com/sharingpolicy), that it is not under consideration for publication elsewhere, that its publication is approved by all authors and tacitly or explicitly by the responsible authorities where the work was carried out, and that, if accepted, it will not be published elsewhere in the same form, in English or in any other language, including electronically without the written consent of the copyright-holder. To verify originality, your article may be checked by the originality detection service CrossCheck http://www.elsevier.com/editors/plagdetect.

Changes to authorship

This policy concerns the addition, deletion, or rearrangement of author names in the authorship of accepted manuscripts:
Before the accepted manuscript is published in an online issue: Requests to add or remove an author, or to rearrange the author names, must be sent to the Journal Manager from the corresponding author of the accepted manuscript and must include: (a) the reason the name should be added or removed, or the author names rearranged and (b) written confirmation (e-mail, fax, letter) from all authors that
they agree with the addition, removal or rearrangement. In the case of addition or removal of authors, this includes confirmation from the author being added or removed. Requests that are not sent by the corresponding author will be forwarded by the Journal Manager to the corresponding author, who must follow the procedure as described above. Note that: (1) Journal Managers will inform the Journal Editors of any such requests and (2) publication of the accepted manuscript in an online issue is suspended until authorship has been agreed.

After the accepted manuscript is published in an online issue: Any requests to add, delete, or rearrange author names in an article published in an online issue will follow the same policies as noted above and result in a corrigendum.

Copyright

Upon acceptance of an article, authors will be asked to complete a 'Journal Publishing Agreement' (for more information on this and copyright, see http://www.elsevier.com/copyright). An e-mail will be sent to the corresponding author confirming receipt of the manuscript together with a 'Journal Publishing Agreement' form or a link to the online version of this agreement.

Subscribers may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions. Permission of the Publisher is required for resale or distribution outside the institution and for all other derivative works, including compilations and translations (please consult http://www.elsevier.com/permissions). If excerpts from other copyrighted works are included, the author(s) must obtain written permission from the copyright owners and credit the source(s) in the article. Elsevier has preprinted forms for use by authors in these cases: please consult http://www.elsevier.com/permissions.

For open access articles: Upon acceptance of an article, authors will be asked to complete an 'Exclusive License Agreement' (for more information see http://www.elsevier.com/OAauthoragreement).

Author rights

As an author you (or your employer or institution) have certain rights to reuse your work. For more information see http://www.elsevier.com/copyright.

Role of the funding source

You are requested to identify who provided financial support for the conduct of the research and/or preparation of the article and to briefly describe the role of the sponsor(s), if any, in study design; in the collection, analysis and interpretation of data; in the writing of the report; and in the decision to submit the article for publication. If the funding source(s) had no such involvement then this should be stated.

Funding body agreements and policies

Elsevier has established a number of agreements with funding bodies which allow authors to comply with their funder's open access policies. Some authors may also be reimbursed for associated publication fees. To learn more about existing agreements please visit http://www.elsevier.com/fundingbodies.

Open access

This journal offers authors a choice in publishing their research:

Open access

- Articles are freely available to both subscribers and the wider public with permitted reuse
- An open access publication fee is payable by authors or on their behalf e.g. by their research funder or institution

Subscription

- Articles are made available to subscribers as well as developing countries and patient groups through our universal access programs (http://www.elsevier.com/access).
- No open access publication fee payable by authors.

Regardless of how you choose to publish your article, the journal will apply the same peer review criteria and acceptance standards.
For open access articles, permitted third party (re)use is defined by the following Creative Commons user licenses:

*Creative Commons Attribution (CC BY)*

Lets others distribute and copy the article, create extracts, abstracts, and other revised versions, adaptations or derivative works of or from an article (such as a translation), include in a collective work (such as an anthology), text or data mine the article, even for commercial purposes, as long as they credit the author(s), do not represent the author as endorsing their adaptation of the article, and do not modify the article in such a way as to damage the author’s honor or reputation.

*Creative Commons Attribution-NonCommercial-NoDerivs (CC BY-NC-ND)*

For non-commercial purposes, lets others distribute and copy the article, and to include in a collective work (such as an anthology), as long as they credit the author(s) and provided they do not alter or modify the article.

The open access publication fee for this journal is **USD 1800**, excluding taxes. Learn more about Elsevier’s pricing policy: [http://www.elsevier.com/openaccesspricing](http://www.elsevier.com/openaccesspricing).

**Language (usage and editing services)**

Please write your text in good English (American or British usage is accepted, but not a mixture of these). Authors who feel their English language manuscript may require editing to eliminate possible grammatical or spelling errors and to conform to correct scientific English may wish to use the English Language Editing service available from Elsevier’s WebShop ([http://webshop.elsevier.com/languageediting/](http://webshop.elsevier.com/languageediting/)) or visit our customer support site ([http://support.elsevier.com](http://support.elsevier.com)) for more information.

**Submission**

Our online submission system guides you stepwise through the process of entering your article details and uploading your files. The system converts your article files to a single PDF file used in the peer-review process. Editable files (e.g., Word, LaTeX) are required to typeset your article for final publication. All correspondence, including notification of the Editor’s decision and requests for revision, is sent by e-mail.

**Submit your article**

Please submit your article via [http://ees.elsevier.com/paid](http://ees.elsevier.com/paid)

**PAID** gives you the opportunity to enrich your article by providing readers with access to relevant statistical R-code and data. To share your R-code and corresponding (example) data set, please submit your R-code and dataset with the manuscript. Multiple files can be submitted. We support the .R format for R-code and .CSV, .XLS, .TXT and .DAT files for datasets. Each R-file and corresponding data set will have to be zipped together and uploaded to online submission system via the “R data” submission category. Recommended size of a single uncompressed file is 100 MB. Please provide a short informative description for each file by filling in the “Description” field when uploading a dataset. Please mention dependencies on R libraries as comment in your R-code.

**Additional Information**

**Manuscripts must be submitted using double-spacing including line and page numbers. These should not exceed the word count provided below:**

**Lengthier reviews or meta-analyses:** The articles with exceptional quality will be considered for publication. Such papers will typically be no more than 10,000 words although longer papers may be submitted and will be considered at the discretion of the editors.

**Review articles:** These articles will be considered for a special review issue, which will appear once a year. Please select Review Article from the dropdown menu upon submission.

**Single study research articles:** Single study research articles can be up to 5000 words.

**Research articles:** Research articles/research articles reporting multiple studies should not exceed 10,000 words.

**Short Communications**: These articles should not exceed 3000 words.

**PREPARATION**
NEW SUBMISSIONS
Submission to this journal proceeds totally online and you will be guided stepwise through the creation
and uploading of your files. The system automatically converts your files to a single PDF file, which
is used in the peer-review process.
As part of the Your Paper Your Way service, you may choose to submit your manuscript as a single file
to be used in the refereeing process. This can be a PDF file or a Word document, in any format or lay-
out that can be used by referees to evaluate your manuscript. It should contain high enough quality
figures for refereeing. If you prefer to do so, you may still provide all or some of the source files at
the initial submission. Please note that individual figure files larger than 10 MB must be uploaded
separately.

References
There are no strict requirements on reference formatting at submission. References can be in any style
or format as long as the style is consistent. Where applicable, author(s) name(s), journal title/book
title, chapter title/article title, year of publication, volume number/book chapter and the pagination
must be present. Use of DOI is highly encouraged. The reference style used by the journal will be
applied to the accepted article by Elsevier at the proof stage. Note that missing data will be highlighted
at proof stage for the author to correct.

Formatting requirements
There are no strict formatting requirements but all manuscripts must contain the essential elements
needed to convey your manuscript, for example Abstract, Keywords, Introduction, Materials and
Methods, Results, Conclusions, Artwork and Tables with Captions.
If your article includes any Videos and/or other Supplementary material, this should be included in
your initial submission for peer review purposes.
Divide the article into clearly defined sections.

Figures and tables embedded in text
Please ensure the figures and the tables included in the single file are placed next to the relevant text
in the manuscript, rather than at the bottom or the top of the file.

REVISED SUBMISSIONS
Use of word processing software
Regardless of the file format of the original submission, at revision you must provide us with an
editable file of the entire article. Keep the layout of the text as simple as possible. Most formatting
codes will be removed and replaced on processing the article. The electronic text should be prepared in
a way very similar to that of conventional manuscripts (see also the Guide to Publishing with Elsevier:
http://www.elsevier.com/guidepublication). See also the section on Electronic artwork.
To avoid unnecessary errors you are strongly advised to use the 'spell-check' and 'grammar-check'
fuctions of your word processor.

Article structure
Subdivision - numbered sections
Divide your article into clearly defined and numbered sections. Subsections should be numbered
1.1 (then 1.1.1, 1.1.2, ..., 1.2, etc. (the abstract is not included in section numbering). Use this
numbering also for internal cross-referencing: do not just refer to 'the text'. Any subsection may be
given a brief heading. Each heading should appear on its own separate line.

Introduction
State the objectives of the work and provide an adequate background, avoiding a detailed literature
survey or a summary of the results.

Material and methods
Provide sufficient detail to allow the work to be reproduced. Methods already published should be
indicated by a reference: only relevant modifications should be described.

Theory/calculation
A Theory section should extend, not repeat, the background to the article already dealt with in the
Introduction and lay the foundation for further work. In contrast, a Calculation section represents a
practical development from a theoretical basis.

Results
Results should be clear and concise.
Discussion
This should explore the significance of the results of the work, not repeat them. A combined Results and Discussion section is often appropriate. Avoid extensive citations and discussion of published literature.

Conclusions
The main conclusions of the study may be presented in a short Conclusions section, which may stand alone or form a subsection of a Discussion or Results and Discussion section.

Appendices
If there is more than one appendix, they should be identified as A, B, etc. Formulae and equations in appendices should be given separate numbering: Eq. (A.1), Eq. (A.2), etc.; in a subsequent appendix, Eq. (B.1) and so on. Similarly for tables and figures: Table A.1; Fig. A.1, etc.

Essential title page information
• Title. Concise and informative. Titles are often used in information-retrieval systems. Avoid abbreviations and formulae where possible.
• Author names and affiliations. Please clearly indicate the given name(s) and family name(s) of each author and check that all names are accurately spelled. Present the authors’ affiliation addresses (where the actual work was done) below the names. Indicate all affiliations with a lower-case superscript letter immediately after the author’s name and in front of the appropriate address. Provide the full postal address of each affiliation, including the country name and, if available, the e-mail address of each author.
• Corresponding author. Clearly indicate who will handle correspondence at all stages of refereeing and publication, also post-publication. Ensure that the e-mail address is given and that contact details are kept up to date by the corresponding author.
• Present/permanent address. If an author has moved since the work described in the article was done, or was visiting at the time, a ‘Present address’ (or ‘Permanent address’) may be indicated as a footnote to that author’s name. The address at which the author actually did the work must be retained as the main, affiliation address. Superscript Arabic numerals are used for such footnotes.

Abstract
An abstract, not exceeding 200 words should constitute the first page of the article.

Graphical abstract
Although a graphical abstract is optional, its use is encouraged as it draws more attention to the online article. The graphical abstract should summarize the contents of the article in a concise, pictorial form designed to capture the attention of a wide readership. Graphical abstracts should be submitted as a separate file in the online submission system. Image size: Please provide an image with a minimum of 531 x 1328 pixels (h x w) or proportionally more. The image should be readable at a size of 5 x 13 cm using a regular screen resolution of 96 dpi. Preferred file types: TIFF, EPS, PDF or MS Office files. See http://www.elsevier.com/graphicalabstracts for examples.
Authors can make use of Elsevier’s Illustration and Enhancement service to ensure the best presentation of their images and in accordance with all technical requirements: Illustration Service.

Highlights
Highlights are mandatory for this journal. They consist of a short collection of bullet points that convey the core findings of the article and should be submitted in a separate editable file in the online submission system. Please use ‘Highlights’ in the file name and include 3 to 5 bullet points (maximum 85 characters, including spaces, per bullet point). See http://www.elsevier.com/highlights for examples.

Keywords
Immediately after the abstract, provide a maximum of 8 keywords, reflecting the essential topics of the article, which may be taken from both the title and the text. These keywords will be used for information retrieval systems and indexing purposes.

Abbreviations
Define abbreviations that are not standard in this field in a footnote to be placed on the first page of the article. Such abbreviations that are unavoidable in the abstract must be defined at their first mention there, as well as in the footnote. Ensure consistency of abbreviations throughout the article.
Acknowledgements
Collate acknowledgements in a separate section at the end of the article before the references and do not, therefore, include them on the title page, as a footnote to the title or otherwise. List here those individuals who provided help during the research (e.g., providing language help, writing assistance or proof reading the article, etc.).

Footnotes
Footnotes should be used sparingly. Number them consecutively throughout the article. Many word processors build footnotes into the text, and this feature may be used. Should this not be the case, indicate the position of footnotes in the text and present the footnotes themselves separately at the end of the article.

Artwork
Electronic artwork
General points
• Make sure you use uniform lettering and sizing of your original artwork.
• Preferred fonts: Arial (or Helvetica), Times New Roman (or Times), Symbol, Courier.
• Number the illustrations according to their sequence in the text.
• Use a logical naming convention for your artwork files.
• Indicate per figure if it is a single, 1.5 or 2-column fitting image.
• For Word submissions only, you may still provide figures and their captions, and tables within a single file at the revision stage.
• Please note that individual figure files larger than 10 MB must be provided in separate source files.
A detailed guide on electronic artwork is available on our website: http://www.elsevier.com/artworkinstructions.

You are urged to visit this site; some excerpts from the detailed information are given here.

Formats
Regardless of the application used, when your electronic artwork is finalized, please ‘save as’ or convert the images to one of the following formats (note the resolution requirements for line drawings, halftones, and line/halftone combinations given below):
• EPS (or PDF): Vector drawings. Embed the font or save the text as ‘graphics’.
• TIFF (or JPG): Color or grayscale photographs (halftones): always use a minimum of 300 dpi.
• TIFF (or JPG): Bitmapped line drawings: use a minimum of 1000 dpi.
• TIFF (or JPG): Combinations bitmapped line/halftone (color or grayscale): a minimum of 500 dpi is required.
• Please do not:
  • Supply files that are optimized for screen use (e.g., GIF, BMP, PICT, WPG); the resolution is too low.
  • Supply files that are too low in resolution.
  • Submit graphics that are disproportionately large for the content.

Figure captions
Ensure that each illustration has a caption. A caption should comprise a brief title (not on the figure itself) and a description of the illustration. Keep text in the illustrations themselves to a minimum but explain all symbols and abbreviations used.

Tables
Tables and figures should be constructed so as to be intelligible without reference to this text, each table and column being provided with a heading. Tables. Captions should be typewritten together on a separate sheet. The same information should not be reproduced in both tables and figures.

References
References should be prepared using the Publication Manual of the American Psychological Association for style. They should be placed on a separate sheet at the end of the paper, double-spaced, in alphabetical order.

References should be quoted in the text by giving the author’s name, followed by the year, e.g. (Hubbard & Ramachandran, 2001) or Hubbard and Ramachandran (2001).

For more than two authors, all names are given when first cited, but when subsequently referred to, the name of the first author is given followed by the words et al., as for example—First citation: Reuter, Roth, Holve and Hennig (2006) but subsequently, Reuter et al. (2006).

This journal should be cited in lists of references as Personality and Individual Differences.

**Web references**

As a minimum, the full URL should be given and the date when the reference was last accessed. Any further information, if known (DOI, author names, dates, reference to a source publication, etc.), should also be given. Web references should be listed separately after the reference list under a different heading - Web References.

**Citation in text**

Please ensure that every reference cited in the text is also present in the reference list (and vice versa). Any references cited in the abstract must be given in full. Unpublished results and personal communications are not recommended in the reference list, but may be mentioned in the text. If these references are included in the reference list they should follow the standard reference style of the journal and should include a substitution of the publication date with either ‘Unpublished results’ or ‘Personal communication’. Citation of a reference as ‘in press’ implies that the item has been accepted for publication.

**References in a special issue**

Please ensure that the words ‘this issue’ are added to any references in the list (and any citations in the text) to other articles in the same Special Issue.

**Reference management software**

Most Elsevier journals have a standard template available in key reference management packages. This covers packages using the Citation Style Language, such as Mendeley ([http://www.mendeley.com/features/reference-manager](http://www.mendeley.com/features/reference-manager)) and also others like EndNote ([http://www.endnote.com/support/enstyles.asp](http://www.endnote.com/support/enstyles.asp)) and Reference Manager ([http://refman.com/support/rmstyles.asp](http://refman.com/support/rmstyles.asp)). Using plug-ins to word processing packages which are available from the above sites, authors only need to select the appropriate journal template when preparing their article and the list of references and citations to these will be formatted according to the journal style as described in this Guide. The process of including templates in these packages is constantly ongoing. If the journal you are looking for does not have a template available yet, please see the list of sample references and citations provided in this Guide to help you format these according to the journal style.

If you manage your research with Mendeley Desktop, you can easily install the reference style for this journal by clicking the link below: [http://open.mendeley.com/use-citation-style/personality-and-individual-differences](http://open.mendeley.com/use-citation-style/personality-and-individual-differences)

When preparing your manuscript, you will then be able to select this style using the Mendeley plug-ins for Microsoft Word or LibreOffice. For more information about the Citation Style Language, visit [http://citationstyles.org](http://citationstyles.org).

**Reference formatting**

There are no strict requirements on reference formatting at submission. References can be in any style or format as long as the style is consistent. Where applicable, author(s) name(s), journal title/book title, chapter title/article title, year of publication, volume number/book chapter and the pagination must be present. Use of DOI is highly encouraged. The reference style used by the journal will be applied to the accepted article by Elsevier at the proof stage. Note that missing data will be highlighted at proof stage for the author to correct. If you do wish to format the references yourself they should be arranged according to the following examples:
Journal abbreviations source
Journal names should be abbreviated according to the List of Title Word Abbreviations: http://www.issn.org/services/online-services/access-to-the-ltwa/.

AudioSlides
The journal encourages authors to create an AudioSlides presentation with their published article. AudioSlides are brief, webinar-style presentations that are shown next to the online article on ScienceDirect. This gives authors the opportunity to summarize their research in their own words and to help readers understand what the paper is about. More information and examples are available at http://www.elsevier.com/audioslides. Authors of this journal will automatically receive an invitation e-mail to create an AudioSlides presentation after acceptance of their paper.

Supplementary material
Elsevier accepts electronic supplementary material to support and enhance your scientific research. Supplementary files offer the author additional possibilities to publish supporting applications, high-resolution images, background datasets, sound clips and more. Supplementary files supplied will be published online alongside the electronic version of your article in Elsevier Web products, including ScienceDirect: http://www.sciencedirect.com. In order to ensure that your submitted material is directly usable, please provide the data in one of our recommended file formats. Authors should submit the material in electronic format together with the article and supply a concise and descriptive caption for each file. For more detailed instructions please visit our artwork instruction pages at http://www.elsevier.com/artworkinstructions.

Open data
This journal supports Open Data, enabling authors to submit any raw (unprocessed) research data with their article for open access publication on ScienceDirect under the CC BY license. For more information, please visit http://www.elsevier.com/about/research-data/open-data.

Submission checklist
Ensure that:
One author has been designated as the corresponding author with contact details:
- E-mail address
- Full postal address
- Telephone number
All necessary files have been uploaded, and contain:
- Keywords
- All figure captions
- All tables (including title, description, footnotes)
Further considerations
- Manuscript has been 'spell-checked' and 'grammar-checked'
- References are in the correct format for this journal
- All references mentioned in the Reference list are cited in the text, and vice versa
- Permission has been obtained for use of copyrighted material from other sources (including the Web)
- Color figures are clearly marked as being intended for color reproduction on the Web (free of charge) and in print, or to be reproduced in color on the Web (free of charge) and in black-and-white in print
- If only color on the Web is required, black-and-white versions of the figures are also supplied for printing purposes
- Title page has to be uploaded separately and it is a mandatory submission item
- Cover letter has to be uploaded as a separate document
- Articles should contain page number
- Ensure that the manuscript including the references are in double line spacing
- Ensure that the author's identity is removed from the original manuscript
- Highlights are submitted in the proper format
- Acknowledgments has to be uploaded as separate document

AFTER ACCEPTANCE
Use of the Digital Object Identifier
The Digital Object Identifier (DOI) may be used to cite and link to electronic documents. The DOI consists of a unique alpha-numeric character string which is assigned to a document by the publisher upon the initial electronic publication. The assigned DOI never changes. Therefore, it is an ideal
medium for citing a document, particularly 'Articles in press' because they have not yet received their full bibliographic information. Example of a correctly given DOI (in URL format; here an article in the journal *Physics Letters B*): http://dx.doi.org/10.1016/j.physletb.2010.09.059

When you use a DOI to create links to documents on the web, the DOIs are guaranteed never to change.

**Proofs**

Proofs will be sent to the author (first-named author if no corresponding author is identified on multi-authored papers) by PDF wherever possible and should be returned within 48 hours of receipt, preferably by e-mail. Corrections should be restricted to typesetting errors, any other amendments may be charged to the author. Any queries should be answered in full. Elsevier will do everything possible to get your article corrected and published as quickly and accurately as possible. Therefore, it is important to ensure that all of your corrections are returned to us in one all-inclusive e-mail or fax. Subsequent additional corrections will not be possible, so please ensure that your first communication is complete. Should you choose to mail your corrections, please return to: Elsevier, Stover Court, Bampfylde Street, Exeter, Devon EX1 2AH, UK.

**Article Based Publishing**

In order to provide you with optimal service and publish your accepted article as quickly as possible, this journal is using the Article Based Publishing system. If you would like to learn more about Article Based Publishing, please see [here](#).

**Offprints**

The corresponding author, at no cost, will be provided with a personalized link providing 50 days free access to the final published version of the article on ScienceDirect. This link can also be used for sharing via email and social networks. For an extra charge, paper offprints can be ordered via the offprint order form which is sent once the article is accepted for publication. Both corresponding and co-authors may order offprints at any time via Elsevier’s WebShop ([http://webshop.elsevier.com/myarticleservices/offprints](http://webshop.elsevier.com/myarticleservices/offprints)). Authors requiring printed copies of multiple articles may use Elsevier WebShop’s 'Create Your Own Book' service to collate multiple articles within a single cover ([http://webshop.elsevier.com/myarticleservices/booklets](http://webshop.elsevier.com/myarticleservices/booklets)).

**Additional information**

**US National Institutes of Health (NIH) voluntary posting/'Public Access Policy'.**

Elsevier facilitates author posting in connection with the voluntary posting request of the NIH (referred to as the NIH ‘Public Access Policy’, see [http://publicaccess.nih.gov](http://publicaccess.nih.gov)) by submitting the peerreviewed author’s manuscript directly to PubMed Central on request from the author, immediately after final publication. Please e-mail us at NIHAuthorrequest@elsevier.com stating that your work has received NIH funding (with the NIH grant/project number(s), as well as name and e-mail address of the Principal Investigator(s)) and that you intend to respond to the NIH request. Upon such confirmation, Elsevier will submit to PubMed Central on your behalf a version of your manuscript that will include peer-review comments, for public access posting 12 months after the final publication date. This will ensure that you will have responded fully to the NIH request policy. There will be no need for you to post your manuscripts directly to PubMed Central, and any such posting is prohibited (although Elsevier will not request that manuscripts authored and posted by US government employees should be taken down from PubMed Central). Individual modifications to this general policy may apply to some Elsevier journals and its society publishing partners.

**AUTHOR INQUIRIES**

You can track your submitted article at [http://www.elsevier.com/track-submission](http://www.elsevier.com/track-submission). You can track your accepted article at [http://www.elsevier.com/trackarticle](http://www.elsevier.com/trackarticle). You are also welcome to contact Customer Support via [http://support.elsevier.com](http://support.elsevier.com).
