Evolutionary problems with energies with linear growth

Johannes Zimmer
(joint work with Martin Kružík)

We study a rate-independent evolution of problems where the energy $W$ is a function of the deformation gradient, $W = W(Du)$, and grows linearly at infinity,

$$c |s| - c_2 \leq W(x, s) \leq C(1 + |s|) \text{ for } x \in \Omega,$$

with constants $0 < c \leq C$. Here, $\Omega \subset \mathbb{R}^n$ is a bounded domain with smooth boundary.

The aim of this note is to sketch a framework within which the existence of a rate-independent process with an energy of type (1) can be proved. Rate-independent processes are understood here in the energetic formulation, i.e., characterised by stability, energy inequality, and compatibility with initial conditions. This is made precise below.

Before moving on to the evolutionary process, we should motivate the functional analytic framework in the static context. The setting needs to be chosen such that oscillation and concentration effects are taken into account. This can be seen in the following toy model, where the task is to minimise the functional

$$\min I(u) := \int_0^1 \left[ \frac{(u'(x))^2}{1 + (u'(x))^4} + \theta^2 |u'(x)| + (u(x) - x)^2 \right] \, dx,$$

with $\theta \geq 0$ among $u \in W^{1,1}(0, 1)$ with $u(0) = 0$. The second term is introduced to make the functional coercive; the third term favours solutions close to the identity. The decisive term is the first one, which becomes minimal for $u'(x) = 0$ or in the limit $u'(x) \to \pm\infty$. One would thus expect approximative solution (minimising sequences) to oscillate between gradient 0 and gradients which become arbitrarily large in modulus. A particular point here is that the minimising sequences thus do not oscillate between finite values for the deformation gradient (as for the toy model $\int_0^1 ((u'(x))^2 - 1)^2 \, dx$ between $\pm 1$), but concentrate mass at $\pm\infty$.

Young measures [5, 1, 3, 4] are an appropriate tool to deal with oscillations, while DiPerna-Majda measures [2] describe the limits of sequences with oscillations and concentrations.

We use DiPerna-Majda measures to describe the evolution of rate-independent processes with linear energies. Let $u: \Omega \to \mathbb{R}^m$ denote the deformation, where $\Omega \subset \mathbb{R}^n$ is a bounded domain with smooth boundary. We write $q := (u, \eta, \lambda)$ for a state; $u$ denotes the deformation, $\eta$ is the associated DiPerna-Majda measure, and $\lambda$ is derived from $\eta$. (To be precise, for a suitable compactification $\beta\mathbb{R}^{m \times n}$ of $\mathbb{R}^{m \times n}$ and for $\eta \cong (\hat{\nu}, \sigma)$ via slicing, we set $\lambda(x) = \int_{\beta\mathbb{R}^{m \times n}} \frac{\Lambda}{1 + |s|} \nu_x(ds)\sigma(x)$ with $\Lambda$ bounded).

The following definitions are natural in the context of DiPerna-Majda measures (we write $\tilde{g}(s) := \frac{g(s)}{1 + |s|}$ and recall that $\beta\mathbb{R}^{m \times n}$ is a suitable compactification of
\( \mathbb{R}^{m \times n} \). The applied body force \( f \) give rise to
\[
F(q) := \int_{\Omega} f(x,t) \cdot u(x) \, \text{d}x \quad \text{and} \quad \dot{F}(t,q) = \int_{\Omega} \frac{\partial f(x,t)}{\partial t} \cdot u(x) \, \text{d}x;
\]
the time-dependent elastic energy \( E(t,q) \)
is
\[
E(t,q) = \int_{\Omega} \tilde{W}(x,s) \eta(\text{d}s) d\text{d}x - \int_{\Omega} f(x,t) \cdot u(x) \, \text{d}x.
\]
(2)
\[\Gamma\] is the energy augmented by a spatial regularisation,
\[
\Gamma(t,q) := E(t,q) + \int_{\Omega} \rho |\nabla \lambda(x)|^2 \, \text{d}x,
\]
with \( \rho > 0 \).

The dissipation distance \( \mathcal{D} \) describes the energetic loss between two states of
the system characterised by \( \eta_1 \) and \( \eta_2 \). We choose \( \mathcal{D}(q_1,q_2) = \int_{\Omega} ||\lambda_1 - \lambda_2|| \, \text{d}x \).

The temporal dissipation is then given by
\[
\text{Diss}(q,[t_1,t_2]) := \sup_{\mathcal{L} \in \mathbb{N}} \left\{ \sum_{l=1}^{L} \mathcal{D} (\eta(\tau_l),\eta(\tau_{l-1})) \mid t_1 = \tau_0 < \cdots < \tau_L = t_2 \right\}.
\]

For given \( q_0 \) in the state space \( Q \), the process \( q: [0,T] \to Q \) is a solution if the following three conditions hold:
1. **Stability**: For every \( t \in [0,T] \), we have
\[ \Gamma(t,q(t)) \leq \Gamma(t,\tilde{q}) + \mathcal{D}(q(t),\tilde{q}) \]
for every \( \tilde{q} \in Q \).
2. **Energy inequality**: For every \( 0 \leq t_1 \leq t_2 \leq T \), we have
\[
\Gamma(t_1,q(t_1)) + \text{Diss}(q,[t_1,t_2]) \leq \Gamma(t_2,q(t_2)) - \int_{t_1}^{t_2} \dot{F}(t,q(t)) \, \text{d}t.
\]
3. **Initial condition**: \( q(0) = q_0 \).

In this setting, the existence of a process satisfying the above conditions can be
proved and suitable regularity assumptions for sufficiently small forces.
