Abstract

On the basis of the explicit formulae for the action of the unitary group of exponentials corresponding to almost solvable extensions of a given closed symmetric operator with equal deficiency indices, we derive a new representation for the scattering matrix for pairs of such extensions. We use this representation to explicitly recover the coupling constants in the inverse scattering problem for a finite non-compact quantum graph with δ-type vertex conditions.

1. Introduction

Over the last eighty years or so, the subject of the mathematical analysis of waves interacting with obstacles and structures ("scattering theory") has served as one of the most impressive examples of bridging abstract mathematics and physics applications, which in turn motivated the development of new mathematical techniques. The pioneering works

Mathematics Subject Classification (2010): 47A45 34L25 81Q35

Keywords: Functional model; Extensions of symmetric operators; Boundary triples; Inverse scattering problems
of von Neumann [57], [58] and his contemporaries during 1930–1950, on the mathematical foundations of quantum mechanics, fuelled the interest of mathematical analysts to formulating and addressing the problems of direct and inverse wave scattering in a rigorous way.

The foundations of the modern mathematical scattering theory were laid by Friedrichs, Kato and Rosenblum [28, 59, 60, 22] and subsequently by Birman and Kreǐn [7], Birman [6], Kato and Kuroda [29] and Pearson [51]. For a detailed exposition of this subject, see [52, 66]. A parallel approach, which provides a connection to the theory of dissipative operators, was developed by Lax and Phillips [40], who analysed the direct scattering problem for a wide class of linear operators in the Hilbert space, including those associated with the multi-dimensional acoustic problem outside an obstacle, using the language of group theory (and, indeed, thereby developing the semigroup methods in operator theory). The associated techniques were also termed “resonance scattering” by Lax and Phillips.

By virtue of the underlying dissipative framework, the above activity set the stage for the applications of non-selfadjoint techniques, such as the functional model for contractions and dissipative operators by Szőkefalvi-Nagy and Foiaş [56], which showed the special rôle in it of the characteristic function of Livşic [42] and allowed Pavlov [50] to construct a spectral form of the functional model for dissipative operators. The connection between this work and the concepts of scattering theory was uncovered by the famous theorem of Adamyan and Arov [1]. In a closely related development, Adamyan and Pavlov [2] established a description for the scattering matrix of a pair of self-adjoint extensions of a symmetric operator (densely or non-densely defined) with finite equal deficiency indices.

Further, Naboko [45] advanced the research initiated by Pavlov, Adamyan and Arov in two directions. Firstly, he generalised Pavlov’s construction of the functional model in its spectral form to the case of non-dissipative operators, and secondly, he established its applicability to the scattering theory for pairs of non-selfadjoint operators. In particular, he provided explicit formulae for the wave operators and scattering matrices of a pair of (in general, non-selfadjoint) operators in the functional model setting. It is remarkable that in this work of Naboko the difference between the so-called stationary and non-stationary scattering approaches disappears.

Our first aim in the present work is to discuss an extension of the approach of Naboko [45], which was formulated for additive perturbations of self-adjoint operators, to the case of both self-adjoint and non-self-adjoint extensions of symmetric operators. Our strategy is based on a version of the functional model of Pavlov and Naboko as developed by Ryzhov [54]. The work [54] stopped short of proving the crucial, from the scattering point of view, theorem on “smooth” vectors and therefore was unable to extend Naboko’s results on the scattering theory to the setting of (in general, non-selfadjoint) extensions of symmetric operators.

Our second aim is, using the above construction, to provide an explicit solution to an open problem of inverse scattering on a finite non-compact quantum graph, namely, the problem of determining matching conditions at the graph vertices. The uniqueness part of this problem has been treated in a preprint by Kostrykin and Schrader [33]. There is also substantial literature on scattering for vector Schrödinger operators on a half-line with matrix potentials, which corresponds to the particular case of a star-graph. Among the latest works on this subject we point out [63], [64], see also references therein, in which scattering is treated in the case of most general matching conditions at the vertex.
The mentioned problem on quantum graphs is a natural generalisation of the classical problem of inverse scattering on the infinite and semi-infinite line, which was solved using the classical integral-operator techniques by Borg [9, 10], Levinson [11], Krein [36, 37, 38], Gelfand and Levitan [23], Marchenko [43], Faddeev [20, 21], Deift and Trubowitz [13]. This body of work has also included the solution to the inverse spectral problem, i.e. the problem of determining the potential in the Schrödinger equation from the spectral data. The inverse scattering problem in these works is reduced to the analysis of the inverse problem based on the Weyl-Titchmarsh $m$-coefficient, and our analysis below benefits from a reduction of the same kind.

In the operator-theoretic context, the $m$-coefficient is generalised to both the classical Dirichlet-to-Neumann map (in the PDE setting), and to the so-called $M$-operator, which takes the form of the Weyl-Titchmarsh $M$-matrix in the case of quantum graphs and, more generally, symmetric operators with finite deficiency indices. This generalisation has been exploited extensively in the study of operators, self-adjoint and non-selfadjoint alike, through the works of Krein’s school in Ukraine on the theory of boundary triples and the associated $M$-operators (Gorbachuk and Gorbachuk [25], Kochubei [31, 32], Derkach and Malamud [15]). In our view, the theory of boundary triples is convenient for the study of quantum graphs, when it can also be viewed as a version of the celebrated Birman-Krein-Višik theory [5, 35, 62].

Quantum graphs, i.e. metric graphs with ordinary differential operators acting on the edges subject to some “coupling” conditions at the graph vertices, see e.g. [4] are known to combine one-dimensional and multidimensional features. Assuming that the graph topology and the lengths of the edges are known, for the operator of second differentiation on all graph edges and $\delta$-type conditions at all graph vertices (see Section 7 for precise definitions), in the present paper we determine the coupling constants at all vertices of a finite graph from the knowledge of its scattering matrix. Our approach to the above problem uses as a starting point the strategy of the work [54] mentioned above, which derived the functional model for dissipative restrictions of “maximal” operators, i.e. the adjoints of symmetric densely-defined operators with equal deficiency indices. The functional-model approach allows us to obtain a new formula for the wave operators for any pair of such restrictions, in terms of the $M$-operator for an appropriate boundary triple on the graph. This formula, in turn, implies an expression for the scattering operator and its spectral representation (“scattering matrix”). The obtained formula is given explicitly in terms of the coupling constants at the graph vertices, which allows us to carry out the inverse procedure of recovering these constants from the knowledge of the scattering matrix. Our approach is a development of the idea of Ershova et al. [16, 17, 18], who studied the inverse spectral problem and the inverse topology problem for quantum graphs using boundary triples and $M$-operators.

The paper is organised as follows. In Section 2 we recall the key points of the theory of boundary triples for extensions of symmetric operators with equal deficiency indices and introduce the associated $M$-operators, following mainly [15] and [54]. In Section 3 we provide several observations that motivate the strategy of our analysis. In Section 4 we recall the functional model for the above family of extensions and characterise the absolutely continuous subspace of $A_\kappa$ as the closure of the set of “smooth” vectors in the model Hilbert space. On the basis of this characterisation, in Section 5 we define the wave operators for a pair from the family $\{A_\kappa\}$ and demonstrate their completeness.
property. This, in combination with the functional model, allows us to obtain formulae
for the scattering operator of the pair (cf. [3]). In Section 6 we describe a convenient rep-
resentation of the scattering operator, namely the “scattering matrix”, which is explicitly
written in terms of the $M$-operator, analogous to the classical notion of the scattering
matrix. All material up to this point is applicable to a general class of operators subject
to the assumptions discussed in Section 2. In Section 7 we recall the concept of a quantum
graph and discuss the implications of the preceding theory for the associated scattering
operator for the pair $(A_\kappa, A_0)$, where $\kappa$ is the parametrising operator as before, now writ-
ten in terms of the “coupling” constants at the graph vertices and $A_0 = A_\kappa|_{\kappa=0}$ is the
“unperturbed” operator with Kirchhoff vertex conditions. Finally, in Section 8 we solve
the inverse scattering problem for a graph with $\delta$-type couplings at the vertices, using the
formulae for the scattering matrix in terms of the $M$-matrix of the graph.

2. Extension theory and boundary triples

Let $\mathcal{H}$ be a separable Hilbert space and denote by $\langle \cdot, \cdot \rangle$ the inner product in this space,
which we consider to be antilinear in the second argument. Let $A$ be a closed symmetric
operator densely defined in $\mathcal{H}$, i.e. $A \subset A^*$, with domain $\text{dom}(A) \subset \mathcal{H}$. For such operators,
all points in the lower and upper half-planes are of regular type with deficiency indices
\[ n_\pm(A) := \dim(\mathcal{H} \ominus \text{ran}(A - zI)) = \dim(\ker(A^* - zI)), \quad z \in \mathbb{C}_\pm. \]
If $A = A^*$ then $A$ is referred to as self-adjoint. A closed operator $L$ is said to be completely non-selfadjoint if there is no subspace reducing $L$ such that the restriction of $L$ to this
subspace is self-adjoint. In this work we consider extensions of a given closed symmetric
operator $A$ with equal deficiency indices, i.e. $n_-(A) = n_+(A)$, and use the theory of boundary triples.

In view of the importance of dissipative operators within the present work, we briefly
recall that a densely defined operator $L$ in $\mathcal{H}$ is called dissipative if
\[ \text{Im} \langle Lf, f \rangle \geq 0 \quad \forall f \in \text{dom}(L). \quad (2.1) \]
For a dissipative operator $L$, the lower half-plane is contained in the set of points of regular
type, i.e.
\[ \mathbb{C}_- \subset \{ z \in \mathbb{C} : \exists C > 0 \ \forall f \in \text{dom}(L) \ \|(L - zI)f\| \geq C \|f\| \}. \]
A dissipative operator $L$ is called maximal if $\mathbb{C}_-$ is actually contained in its resolvent set
$\rho(L) := \{ z \in \mathbb{C} : (L - zI)^{-1} \in \mathcal{B}(\mathcal{H}) \}$. ($\mathcal{B}(\mathcal{H})$ denotes the space of bounded operators
defined on the whole Hilbert space $\mathcal{H}$). Clearly, a maximal dissipative operator is closed.

We next describe the boundary triple approach to the extension theory of symmetric
operators with equal deficiency indices (see in [14] a review of the subject). This approach
is particularly useful in the study of self-adjoint extensions of differential operators of
second order.

**Definition 1.** For a closed symmetric operator $A$ with equal deficiency indices, consider
the linear mappings $\Gamma_1 : \text{dom}(A^*) \to \mathcal{K}$, $\Gamma_0 : \text{dom}(A^*) \to \mathcal{K}$, where $\mathcal{K}$ is an auxiliary
separable Hilbert space, such that

\[ \langle A^* f, g \rangle_{\mathcal{H}} - \langle f, A^* g \rangle_{\mathcal{H}} = \langle \Gamma_1 f, \Gamma_0 g \rangle_{\mathcal{K}} - \langle \Gamma_0 f, \Gamma_1 g \rangle_{\mathcal{K}}; \]  

(2.2)

The mapping \( \text{dom}(A^*) \ni f \mapsto \begin{pmatrix} \Gamma_1 f \\ \Gamma_0 f \end{pmatrix} \in \mathcal{K} \oplus \mathcal{K} \) is surjective.

Then the triple \((\mathcal{K}, \Gamma_1, \Gamma_0)\) is said to be a boundary triple for \(A^*\).

In this work we consider almost solvable extensions \(A_B\) for which there exists a triple \((\mathcal{K}, \Gamma_1, \Gamma_0)\) and \(B \in \mathcal{B}(\mathcal{K})\) such that

\[ f \in \text{dom}(A_B) \iff \Gamma_1 f = B \Gamma_0 f. \]  

(2.3)

The following assertions, written in slightly different terms, can be found in [31, Thm. 2] and [26, Chap. 3 Sec. 1.4] (see also [30, Thm. 2.3], [54, Thm. 1.1], and [55, Sec. 14] for a closer formulation). We compile them in the next proposition for easy reference.

**Proposition 2.1.** Let \(A\) be a closed symmetric operator with equal deficiency indices and let \((\mathcal{K}, \Gamma_1, \Gamma_0)\) be the boundary triple for \(A^*\). Assume that \(A_B\) is an almost solvable extension. Then the following statements hold:

1. \( f \in \text{dom}(A) \) if and only if \( \Gamma_1 f = \Gamma_0 f = 0 \).
2. \( A_B \) is maximal, i.e., \( \rho(A_B) \neq \emptyset \).
3. \( A_B^* = A_B^* \).
4. \( A_B \) is dissipative if and only if \( B \) is dissipative.
5. \( A_B \) is self-adjoint if and only if \( B \) is self-adjoint.

**Definition 2.** The function \( M : \mathbb{C}^{-} \cup \mathbb{C}^{+} \to \mathcal{B}(\mathcal{H}) \) such that

\[ M(z) \Gamma_0 f = \Gamma_1 f \quad \forall f \in \ker(A^* - zI) \]

is the Weyl function of the boundary triple \((\mathcal{K}, \Gamma_1, \Gamma_0)\) for \(A^*\), where \(A\) is assumed to be as in Proposition 2.1.

The Weyl function defined above has the following properties [15].

**Proposition 2.2.** Let \(M\) be a Weyl function of the boundary triple \((\mathcal{K}, \Gamma_1, \Gamma_0)\) for \(A^*\), where \(A\) is a closed symmetric operator with equal deficiency indices. Then the following statements hold:

1. \( M : \mathbb{C} \setminus \mathbb{R} \to \mathcal{B}(\mathcal{K}) \).
2. \( M \) is a \( \mathcal{B}(\mathcal{K}) \)-valued double-sided \( \mathcal{R} \)-function [27], that is,

\[ M(z)^* = M(\overline{z}) \quad \text{and} \quad \text{Im}(z) \text{Im}(M(z)) > 0 \quad \text{for} \quad z \in \mathbb{C} \setminus \mathbb{R}. \]

3. The spectrum of \(A_B\) coincides with the set of points \( z_0 \in \mathbb{C} \) such that \((M - B)^{-1}\) does not admit analytic continuation into \(z_0\).
We next lay out the notation for some of the main objects in our analysis. In the auxiliary Hilbert space $\mathcal{K}$, choose a bounded positive self-adjoint operator $\alpha$ so that the operator

$$B_\kappa := \frac{\alpha \kappa \alpha}{2}$$

(2.4)

belongs to $\mathcal{B}(\mathcal{K})$, where $\kappa$ is a bounded operator in $\mathcal{K}$. In what follows, we deal with almost solvable extensions of a given symmetric operator $A$ that are generated by $B_\kappa$ via (2.3). It is always assumed that the deficiency indices of $A$ are equal and that some boundary triple $(\mathcal{K}, \Gamma_1, \Gamma_0)$ for $A^*$ is fixed. In order to streamline the formulae, we write

$$A_\kappa := A_{B_\kappa}.$$ 

(2.5)

Here $\kappa$ should be understood as a parameter for a family of almost solvable extensions of $A$. Note that if $\kappa$ is self-adjoint then so is $B_\kappa$ and, hence by Proposition 2.1(5), $A_\kappa$ is self-adjoint. Note also that $A_iI$ is maximal dissipative, again by Proposition 2.1.

**Definition 3.** The characteristic function of the operator $A_iI$ is the operator-valued function $S$ on $\mathbb{C}_+$ given by

$$S(z) := I + i\alpha \left( B_i^\ast I - M(z) \right)^{-1} \alpha, \quad z \in \mathbb{C}_+. \quad (2.6)$$

**Remark 1.** The function $S$ is analytic in $\mathbb{C}_+$ and, for each $z \in \mathbb{C}_+$, the mapping $S(z) : \mathcal{K} \rightarrow \mathcal{K}$ is a contraction. Therefore, $S$ has nontangential limits almost everywhere on the real line in the strong topology [56], which we henceforth denote by $S(k), k \in \mathbb{R}$.

**Remark 2.** When $\alpha = \sqrt{2}I$, which is the case of our application to finite quantum graphs, a straightforward calculation yields that $S(z)$ is the Cayley transform of $M(z)$, i.e.

$$S(z) = \left( M(z) - iI \right) \left( M(z) + iI \right)^{-1}. \quad (2.7)$$

### 3. General remarks on our approach

Our approach to mathematical scattering theory for extensions of closed symmetric operators (direct and inverse) will be based on the functional model for a family of almost solvable extensions of the given minimal symmetric operator. Our choice of this method is based on the following considerations:

1) We would like to consider scattering problems where at least one of the two operators of the pair is non-selfadjoint. In contrast, the classical scattering results only pertain to pairs of self-adjoint operators: even the definition of $\exp(iLt)$ in the case of non-selfadjoint $L$ needs to be clarified. While there are various ways to construct functional calculus for non-uniformly bounded groups, say the Riesz-Dunford calculus, the most attractive of them for us is via developing a functional model where the exponent is represented by an operator of multiplication on a linear set dense in the absolutely continuous subspace of its generator. The “symmetric Pavlov model” [50], which we describe in Section 4, provides such an approach.

---

1 Clearly, the assumption that $\ker(\alpha) = \{0\}$ is without loss of generality, by a suitable modification of $\kappa$ if necessary.
2) Naboko [45] has shown how to construct mathematical scattering for a class of non-selfadjoint operators in the “additive” case \( L = A + iV \), where \( A, V \) are self-adjoint operators. This kind of method offers some advantages in comparison with other techniques: a) the difference between stationary and non-stationary theories disappears, in the sense that the same construction yields explicit expressions for both; b) the scattering operator is represented in a concise form, which, in particular, immediately yields a formula for the spectral representation in the eigenfunction basis of the unperturbed self-adjoint operator (“scattering matrix”).

3) It has to be pointed out that the seemingly non-selfadjoint approach due to Naboko contains the self-adjoint setting as its particular case, and when applied this way it yields all the classical results (e.g. Pearson Theorem, Birman-Krein-Kuroda Theorem, as well as their generalisations). In this self-adjoint setting this approach proves to be consistent with the “smooth” scattering theory (see [60]). As in the case of the latter, the principal rôle in Naboko’s construction is played by a linear dense subset of the absolutely continuous subspace (“smooth” vectors), which in the self-adjoint case is described by the so-called Rosenblum Lemma [60]. In the non-self-adjoint case the corresponding linear dense subset is identified by the property that the resolvent acts on it as the resolvent of the operator of multiplication in the symmetric Pavlov representation, cf. (4.9). This, in turn, facilitates the derivation of explicit formulae for wave operators on these dense sets of smooth vectors. The construction of the wave operators is then completed by passing to a closure.

In what follows we briefly describe the approach introduced above and the results obtained on this way, essentially building up on the earlier results pertaining to the analysis of non-self-adjoint extensions, due to Ryzhov. These allow us to generalise Naboko’s construction of wave operators and scattering matrices to the case studied in the present paper. In order to deal with the family of extensions \( \{A_\kappa\} \) of the operator \( A \) (where the parameter \( \kappa \) is itself an operator, see notation immediately following Proposition 2.2), we first construct a functional model of its particular dissipative extension. This is done following the Pavlov-Naboko procedure, which in turn stems from Sz.-Nagy-Foiaș functional model. This allows us to obtain a simple model for the whole family \( \{A_\kappa\} \), in particular yielding a possibility to apply it to the scattering theory for certain pairs of operators in \( \{A_\kappa\} \), including both the cases when these operators are self-adjoint and non-selfadjoint. In view of transparency, we try to reduce the technicalities to the bare minimum, at the same time pointing out that the corresponding complete proofs of the necessary statements can be found in [12].

4. Functional model

Following [45], we introduce a Hilbert space serving as a functional model for the family of operators \( A_\kappa \). This functional model was constructed for completely non-selfadjoint maximal dissipative operators in [50, 48, 49] and further developed in [45]. Next we recall some related necessary information. In what follows, in various formulae, we use the subscript “±” to indicate two different versions of the same formula in which the subscripts “+” and “−” are taken individually.

A \( \mathcal{K} \)-valued function \( f \), analytic on \( \mathbb{C}_\pm \), is said to be in the Hardy class \( H^2_\pm(\mathcal{K}) \) if (cf.
Whenever \( f \in H^2_\pm(\mathcal{K}) \), the left-hand side of the above inequality defines \( \|f\|_{H^2_\pm(\mathcal{K})}^2 \). We use the notation \( H^2_\pm \) and \( H^2_\mp \) for the usual Hardy spaces of \( \mathbb{C} \)-valued functions. Any element in the Hardy spaces \( H^2_\pm(\mathcal{K}) \) can be associated with its boundary values in the topology of \( \mathcal{K} \), which exist almost everywhere on the real line. The spaces of boundary functions of \( H^2_\pm(\mathcal{K}) \) are denoted by \( \hat{H}^2_\pm(\mathcal{K}) \), and they are subspaces of \( L^2(\mathbb{R}, \mathcal{K}) \). By the Paley-Wiener theorem [53, Sec. 4.8, Thm. E]), these subspaces are the orthogonal complements of each other (i.e., \( L^2(\mathbb{R}, \mathcal{K}) = \hat{H}^2_+(\mathcal{K}) \oplus \hat{H}^2_-(\mathcal{K}) \)).

As mentioned above, the characteristic function \( S \) has non-tangential limits almost everywhere on the real line in the strong topology. Thus, for a two-component vector function \( \tilde{g} \) taking values in \( \mathcal{K} \oplus \mathcal{K} \), one can consider the integral

\[
\int_{\mathbb{R}} \left\langle \begin{pmatrix} I & S^*(s) \\ S(s) & I \end{pmatrix}, \begin{pmatrix} \tilde{g}(s) \\ g(s) \end{pmatrix}, \begin{pmatrix} \tilde{g}(s) \\ g(s) \end{pmatrix} \right\rangle_{\mathcal{K} \oplus \mathcal{K}} ds,
\]

which is always nonnegative, due to the contractive properties of \( S \). The space

\[
\mathcal{F} := L^2\left( \mathcal{K} \oplus \mathcal{K}; \begin{pmatrix} I & S^* \\ S & I \end{pmatrix} \right)
\]

is the completion of the linear set of two-component vector functions \( \tilde{g} : \mathbb{R} \rightarrow \mathcal{K} \oplus \mathcal{K} \) in the norm (4.1), factored with respect to vectors of zero norm. Naturally, not every element of the set can be identified with a pair \( \tilde{g} \) of two independent functions. Still, in what follows we keep the notation \( \tilde{g} \) for the elements of this space.

Another consequence of the contractive properties of the characteristic function \( S \) is that for \( \tilde{g}, g \in L^2(\mathbb{R}, \mathcal{K}) \) one has

\[
\left\| \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} \right\|_{\mathcal{F}} \geq \left\| \tilde{g} + S^*g \right\|_{L^2(\mathbb{R}, \mathcal{K})} \left\| S\tilde{g} + g \right\|_{L^2(\mathbb{R}, \mathcal{K})}.
\]

Thus, for every Cauchy sequence \( \{\tilde{g}_n\}_{n=1}^\infty \) with respect to the \( \mathcal{F} \)-topology, such that \( \tilde{g}_n, g_n \in L^2(\mathbb{R}, \mathcal{K}) \) for all \( n \in \mathbb{N} \), the limits of \( \tilde{g}_n + S^*g_n \) and \( S\tilde{g}_n + g_n \) exist in \( L^2(\mathbb{R}, \mathcal{K}) \), so that the objects \( \tilde{g} + S^*g \) and \( S\tilde{g} + g \) can always be treated as \( L^2(\mathbb{R}, \mathcal{K}) \) functions.

Furthermore, consider the orthogonal subspaces of \( \mathcal{F} \)

\[
D_- := \begin{pmatrix} 0 \\ \hat{H}^2_-(\mathcal{K}) \end{pmatrix}, \quad D_+ := \begin{pmatrix} \hat{H}^2_+(\mathcal{K}) \\ 0 \end{pmatrix},
\]

and define the space \( K := \mathcal{F} \oplus (D_- \oplus D_+) \), which is characterised as follows, see e.g. [48, 49]:

\[
K = \left\{ \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} : \tilde{g} + S^*g \in \hat{H}^2_+(\mathcal{K}), S\tilde{g} + g \in \hat{H}^2_-(\mathcal{K}) \right\}.
\]
The orthogonal projection $P_K$ onto the subspace $K$ is given by (see e.g. [44])

$$P_K \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} = \begin{pmatrix} \tilde{g} - P_+(\tilde{g} + S^*g) \\ g - P_-(S\tilde{g} + g) \end{pmatrix},$$

(4.5)

where $P_\pm$ are the orthogonal Riesz projections in $L^2(K)$ onto $\tilde{H}_\pm^2(K)$.

A completely non-selfadjoint dissipative operator admits [56] a self-adjoint dilation. The dilation $A = A^*$ of the operator $A_{iI}$ is constructed following Pavlov’s procedure [48, 50, 49]: it is defined in the Hilbert space $H = L^2(\mathbb{R}_-, K) \oplus \mathcal{H} \oplus L^2(\mathbb{R}_+, K)$, so that

$$P_H(A - zI)^{-1} \mid_H = (A_{iI} - zI)^{-1}, \quad z \in \mathbb{C}_-.$$  

As in the case of additive non-selfadjoint perturbations [45], Ryzhov established in [54, Thm. 2.3] that $\mathcal{H}$ serves as the functional model for the dilation $A$, i.e. there exists an isometry $\Phi : \mathcal{H} \to \mathcal{H}$ such that $A$ is transformed into the operator of multiplication by the independent variable: $\Phi(A_{iI} - zI)^{-1} = (\cdot - z)^{-1}\Phi$. Furthermore, under this isometry

$$\Phi \mid_H \mathcal{H} = K$$

unitarily, where $\mathcal{H}$ is understood as being embedded in $\mathcal{H}$ in the natural way, i.e.

$$\mathcal{H} \ni h \mapsto 0 \oplus h \oplus 0 \in \mathcal{H}.$$  

In what follows we keep the label $\Phi$ for the restriction $\Phi \mid_H$, in hope that it does not lead to confusion.

Following the ideas of Naboko, in the functional model space $\mathcal{H}$ consider two subspaces

$$\mathcal{N}_{\pm}^{\kappa} := \left\{ \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} \in \mathcal{H} : P_\pm \left( \chi_+^\kappa(\tilde{g} + S^*g) + \chi_-^\kappa(S\tilde{g} + g) \right) = 0 \right\},$$

(4.6)

where

$$\chi_\pm^\kappa := \frac{I \pm i\kappa}{2}.$$  

These subspaces have a characterisation in terms of the resolvent of the operator $A^{\kappa}_x$, whose proof, see [12], follows the approach of [45, Thm. 4].

**Theorem 4.1 ([12]).** The following characterisation holds:

$$\mathcal{N}_{\pm}^{\kappa} = \left\{ \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} \in \mathcal{H} : \Phi(A_{iI} - zI)^{-1}\Phi^*P_K \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} = P_K \begin{pmatrix} \tilde{g} \\ g \end{pmatrix} \text{ for all } z \in \mathbb{C}_\pm \right\}.$$  

(4.7)

Consider also the counterparts of $\mathcal{N}_{\pm}^{\kappa}$ in the original Hilbert space $\mathcal{H}$:

$$\tilde{N}_{\pm}^{\kappa} := \Phi^*P_K \mathcal{N}_{\pm}^{\kappa},$$

(4.8)

which are linear sets albeit not necessarily subspaces. In a way similar to [45], we define the set

$$\tilde{N}_e^{\kappa} := \tilde{N}_+^{\kappa} \cap \tilde{N}_-^{\kappa}$$

of so-called smooth vectors and its closure $N_e^{\kappa} := \text{clos}(\tilde{N}_e^{\kappa})$. This proves to be suitable for
the description of the absolutely continuous subspace and, therefore, for the construction of the wave operators.

**Definition 4.** For a symmetric operator \( A \), in the case of a non-selfadjoint extension \( A_\kappa \) the absolutely continuous subspace \( H_{ac}(A_\kappa) \) is defined by the formula \( H_{ac}(A_\kappa) = N_\kappa^e \).

The next statement, the proof of which is given in [12], motivates the above definition.

**Theorem 4.2** (Self-adjoint case, see [12]). Assume that \( \kappa = \kappa^* \) (equivalently, \( A_\kappa = A_\kappa^* \)) and let \( \alpha \Gamma_0(A_\kappa - zI)^{-1} \) be a Hilbert-Schmidt operator for at least one point \( z \in \rho(A_\kappa) \). If \( A \) is completely non-selfadjoint, then \( N_\kappa^e = H_{ac}(A_\kappa) \).

Definition 4 follows in the footsteps of the corresponding definition by Naboko [45] in the case of additive perturbations. In particular, an argument similar to [45, Corollary 1] shows that for the functional model image of \( \tilde{N}_\kappa^e \) the following representation holds:

\[
\Phi \tilde{N}_\kappa^e = \left\{ P_K \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) : \begin{array}{c} \\
\end{array} \begin{array}{c} \tilde{g} \\ g \end{array} \mbox{ satisfies } \Phi(A_\kappa - zI)^{-1} \Phi^* P_K \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) = P_K \left( \begin{array}{c} 1 \\ -z \end{array} \right) \begin{array}{c} \tilde{g} \\ g \end{array} \forall z \in \mathbb{C} \end{array} \right\},
\]

(4.9)

(Note that the inclusion of the right-hand side of (4.9) into \( \Phi \tilde{N}_\kappa^e \) follows immediately from Theorem 4.1.) Further, we arrive at an equivalent description (cf. (4.6)):

\[
\Phi \tilde{N}_\kappa^e = \left\{ P_K \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) : \begin{array}{c} \\
\end{array} \begin{array}{c} \tilde{g} \\ g \end{array} \mbox{ satisfies } \chi_{\kappa^+}^+(\tilde{g} + S^*g) + \chi_{\kappa^-}(S\tilde{g} + g) = 0 \right\}.
\]

(4.10)

The representations (4.9), (4.10) illustrate the rôle of the subspace of smooth vectors as the subspace in whose image under the isometry \( \Phi \) the operator \( A_\kappa \) acts as multiplication by the independent variable. This property is crucial in the derivation of the formulae for wave operators of pairs from the family \( \{A_\kappa\} \), which we present in the next section and which are subsequently used in the solution of the inverse problem for quantum graphs in Sections 7, 8.

### 5. Wave and scattering operators

The results discussed above allow us to calculate the wave operators for any pair \( A_\kappa_1, A_\kappa_2 \), where \( A_\kappa_1 \) and \( A_\kappa_2 \) are operators in the class introduced in Section 2. For simplicity, and bearing in mind the application of the abstract construction to the problem described in Sections 7 and 8 in what follows we set \( \kappa_2 = 0 \) and write \( \kappa \) instead of \( \kappa_1 \). Note that \( A_0 \) is a self-adjoint operator, which is convenient for presentation purposes.

We begin by recalling the model representation for the function \( \exp(iA_\kappa t), t \in \mathbb{R} \), of the operator \( A_\kappa \), evaluated on the set of smooth vectors \( \tilde{N}_\kappa^e \), as well as a proposition describing such vectors in \( \tilde{N}_\kappa^e \) and \( \tilde{N}_0^e \) that the difference between their respective dynamics vanishes as \( t \to -\infty \).

**Proposition 5.1.** ([45, Prop. 2]) For all \( t \in \mathbb{R} \) and all \( \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) \) such that \( \Phi^* P_K \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) \in \tilde{N}_\kappa^e \) one has

\[
\Phi \exp(iA_\kappa t) \Phi^* P_K \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right) = P_K \exp(ikt) \left( \begin{array}{c} \tilde{g} \\ g \end{array} \right).
\]
Proposition 5.2. ([45, Section 4]) If $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^\kappa$ and $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^0$ (with the same element $\tilde{g}$), then

$$\left\| \exp(-iA_\kappa t)\Phi^* P_K(\tilde{g}) - \exp(-iA_0 t)\Phi^* P_K(\tilde{g}) \right\|_{\mathcal{B}} \xrightarrow{t \to -\infty} 0.$$ 

It follows from Proposition 5.2 that whenever $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^\kappa$ and $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^0$ (with the same second component $g$), one formally has

$$\lim_{t \to -\infty} e^{iA_0 t} e^{-iA_\kappa t} \Phi^* P_K(\tilde{g}) = \Phi^* P_K(\tilde{g}) = \Phi^* P_K\left(-\frac{(I + S)^{-1}(I + S^*)g}{g}\right),$$

where in the last equality we use the inclusion $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^0$, which by (4.10) yields $\tilde{g}' + S g + S \tilde{g}' + g = 0$.

In what follows we use the standard definition of wave operators, see e.g. [28], allowing the operator $A_\kappa$ to be non-selfadjoint:

$$W_\pm(A_0, A_\kappa) := \text{s-lim}_{t \to \pm \infty} e^{iA_\kappa t} e^{-iA_0 t} P_{ac}.$$

(5.1)

In the above formulae, we denote by $P_{ac}, P_{ac}^0$ the projections onto the absolutely continuous subspace of $A_\kappa$, see Definition 1[1] and the absolutely continuous subspace of the self-adjoint operator $A_0$, respectively.

It follows that for $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^\kappa$ one has

$$W_-(A_0, A_\kappa) \Phi^* P_K(\tilde{g}) = \Phi^* P_K\left(-\frac{(I + S)^{-1}(I + S^*)g}{g}\right).$$

(5.2)

One argues in a similar way in the case of the wave operator $W_+(A_0, A_\kappa)$, as well as in the case of the wave operators $W_\pm(A_\kappa, A_0)$, which we define by

$$\left\| e^{-iA_\kappa t} W_\pm(A_\kappa, A_0) \Phi^* P_K(\tilde{g}) - e^{-iA_0 t} \Phi^* P_K(\tilde{g}) \right\|_{\mathcal{B}} \xrightarrow{t \to \pm \infty} 0, \quad \Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^0.$$ 

Theorem 5.3 ([12]). Let $A$ be a closed, symmetric, completely non-selfadjoint operator with equal deficiency indices and consider its extension $A_\kappa$, as described in Section 2 under the assumption that $A_\kappa$ has at least one regular point in $\mathbb{C}_+$ and in $\mathbb{C}_-$. If $S - I$ is compact in $\mathbb{C}_\pm$, then the wave operators $W_\pm(A_0, A_\kappa)$ exist on dense sets in $N_e^\kappa$ and for all $\Phi^* P_K(\tilde{g}) \in \widetilde{N}_e^\kappa$ one has (5.2) and

$$W_+(A_0, A_\kappa) \Phi^* P_K(\tilde{g}) = \Phi^* P_K\left(-\frac{\tilde{g}}{(I + S^*)^{-1}(I + S)\tilde{g}}\right).$$

(5.3)

Similarly, the wave operators and $W_\pm(A_\kappa, A_0)$ exist on dense sets in $\mathcal{H}_{ac}(A_0)$ and for all

---

2Despite the fact that $(\tilde{g}) \in \mathcal{B}$ is nothing but a symbol, still $\tilde{g}$ and $g$ can be identified with vectors in certain $L^2(K)$ spaces with operators “weights”, see details below in Section 6. Further, we recall that even then for $(\tilde{g}) \in \mathcal{B}$, the components $\tilde{g}$ and $g$ are not, in general, independent of each other.
\[ \Phi^* P_K(\tilde{g}) \in \tilde{N}_{\epsilon}^0 \] one has

\[ W_-(A_\varkappa, A_0) \Phi^* P_K(\tilde{g}) = \Phi^* P_K \left( -(I + \chi_\varkappa(S - I))^{-1}(I + \chi_\varkappa(S^* - I))g \right), \quad (5.4) \]

\[ W_+(A_\varkappa, A_0) \Phi^* P_K(\tilde{g}) = \Phi^* P_K \left( -(I + \chi_\varkappa(S^* - I))^{-1}(I + \chi_\varkappa(S - I))\tilde{g} \right), \quad (5.5) \]

The ranges of \( W_\pm(A_0, A_\varkappa) \) and \( W_\pm(A_\varkappa, A_0) \) are dense in \( \mathcal{H}_{ac}(A_0) \) and \( N_\varkappa^\varepsilon \), respectively.\(^3\)

**Sketch of the proof.** In order to rigorously justify the above formal derivation of (5.2)–(5.5), i.e. in order to prove the existence and completeness of the wave operators, one needs to show that the right-hand sides of the formulae (5.2)–(5.5) make sense on dense subsets of the corresponding absolutely continuous subspaces. Noting that (5.2)–(5.5) have the form identical to the expressions for wave operators derived in [45, Section 4], [47], this justification is an appropriate modification of the argument of [47].

Indeed, consider the formula (5.2). Here one needs to attribute a correct sense to the expression \( (I + S(k))^{-1} \) a.e. on the real line. Let \( S(z) - I \) satisfy the assumption of the theorem. Then, using the strategy of [47], one has non-tangential boundedness of \( (I + S(z))^{-1} \) for almost all points of the real line. On the other hand, the latter inverse can be computed in \( \mathbb{C}_+ \):

\[ (I + S(z))^{-1} = \frac{1}{2} (I + i\alpha M(z)^{-1} \alpha/2). \]

It follows from the analytic properties of \( M(z) \) that the inverse \( (I + S(z))^{-1} \) exists everywhere in the upper half-plane. Thus, [47] yields that \( (I + S(z))^{-1} \) is \( \mathbb{R} \)-a.e. non-tangentially bounded and it admits measurable non-tangential limits in the strong operator topology almost everywhere on \( \mathbb{R} \). As it is easily seen, these limits must then coincide with \( (I + S(k))^{-1} \) for almost all \( k \in \mathbb{R} \).

The presented argument allows one to verify the correctness of the formula (5.2). Indeed, consider \( \mathbbm{1}_n(k) \), the indicator of the set \( \{ k \in \mathbb{R} : ||(I + S(k))^{-1}|| \leq n \} \). Clearly, \( \mathbbm{1}_n(k) \to 1 \) as \( n \to \infty \) for almost all \( k \in \mathbb{R} \). Next, suppose that \( P_K(\tilde{g}, g) \in \tilde{N}_\varepsilon^\varkappa \). Then \( P_K \mathbbm{1}_n(\tilde{g}, g) \) is also a smooth vector and

\[ \left( -(I + S)^{-1} \mathbbm{1}_n(I + S^*)g \right) \mathbbm{1}_n g \in \mathcal{S}. \]

It follows, by the Lebesgue dominated convergence theorem, that the set of vectors \( P_K \mathbbm{1}_n(\tilde{g}, g) \) is dense in \( N_\varepsilon^\varkappa \).

The remaining three wave operators are treated in a similar way, see the complete details in [12]. Finally, the density of the range of the four wave operators follows from the density of their domains, by a standard inversion argument, see e.g. [66]. \( \square \)

\(^3\)In the case when \( A_\varkappa \) is self-adjoint, or, in general, the named wave operators are bounded, the claims of the theorem are equivalent (by the classical Banach-Steinhaus theorem) to the statement of the existence and completeness of the wave operators for the pair \( A_0, A_\varkappa \). Sufficient conditions of boundedness of these wave operators are contained in e.g. [45, Section 4], [47] and references therein.
Remark 3 ([12]). 1. The condition of the above theorem that \( S(z) - I \) is compact in \( \mathbb{C}_+ \) is satisfied [24] [12], as long as the scalar function \( \|\alpha M(z)^{-1}a\|_{\mathcal{B}_p} \) is nontangentially bounded almost everywhere on the real line for some \( p < \infty \), where \( \mathcal{S}_p \), \( p \in (0, \infty] \), are the standard Schatten – von Neumann classes of compact operators.

2. An alternative sufficient condition is the condition \( \alpha \in \mathcal{S}_2 \) (and therefore \( B_{\infty} \in \mathcal{S}_1 \)), or, more generally, \( \alpha M(z)^{-1}\alpha \in \mathcal{S}_1 \), see [46] for details.

3. Following from the analysis above, the existence and completeness of the wave operators for the pair \( A_{\kappa}, A_{0} \) is closely linked to the condition of \( \alpha \) having a “relative Hilbert-Schmidt property” with respect to \( M(z) \). Recalling that \( B_{\kappa} = \alpha z \kappa / 2 \), this is not always feasible to expect. Nevertheless, by appropriately modifying the boundary triple, the situation can often be rectified. For example, if \( C_{\kappa} = C_{0} + \alpha z \kappa / 2 \), where \( C_{0} \) and \( z \) are bounded and \( \alpha \in \mathcal{S}_2 \), replaces the operator \( B_{\kappa} \) in (2.4), then one “shifts” the boundary triple: \( \hat{\Gamma}_0 = \Gamma_0, \hat{\Gamma}_1 = \Gamma_1 - C_0 \Gamma_0 \). One thus obtains that in the new triple \( (\kappa, \hat{\Gamma}_0, \hat{\Gamma}_1) \) the operator \( A_{\kappa} \) coincides with the extension corresponding to the boundary operator \( B_{\kappa} = \alpha z \kappa / 2 \), whereas the Weyl-Titchmarsh function \( M(z) \) undergoes a shift to the function \( M(z) - C_0 \). The proof of Theorem 6.1 remains intact, while Part 2 of this remark yields that the condition \( \alpha (M(z) - C_0)^{-1}\alpha \in \mathcal{S}_1 \) guarantees the existence and completeness of the wave operators for the pair \( A_{C_0}, A_{C_{\kappa}} \). The fact that the operator \( A_{0} \) here is replaced by the operator \( A_{C_0} \) reflects the standard argument that the complete scattering theory for a pair of operators requires that the operators forming this pair are “close enough” to each other.

The scattering operator \( \Sigma \) for the pair \( A_{\kappa}, A_{0} \) is defined by

\[
\Sigma = W_{+}^{-1}(A_{\kappa}, A_{0})W_{-}(A_{\kappa}, A_{0}).
\]

The formulae (5.2) – (5.5) lead (see (cf. [15])) to the following formula for the action of \( \Sigma \) in the model representation:

\[
\Phi \Sigma \Phi^* P_K \begin{pmatrix} \bar{g} \\ g \end{pmatrix} = P_K \begin{pmatrix} - (I + \chi_{\kappa}(S - I))^{-1}(I + \chi_{\kappa}^+(S^* - I))g \\ (I + S^*)^{-1}(I + S)(I + \chi_{\kappa}(S - I))^{-1}(I + \chi_{\kappa}^+(S^* - I))g \end{pmatrix}, \quad (5.6)
\]

whenever \( \Phi^* P_K \begin{pmatrix} \bar{g} \\ g \end{pmatrix} \in \tilde{N}_e^0 \). This representation holds on a dense linear set in \( \tilde{N}_e^0 \) within the conditions of Theorem 5.3 which guarantees that all the objects on the right-hand side of the formula (5.6) are correctly defined.

6. Spectral representation for the absolutely continuous part of \( A_0 \)

The identity

\[
\left\| P_K \begin{pmatrix} \bar{g} \\ g \end{pmatrix} \right\|^2_{\tilde{H}} = \langle (I - S^*S)\bar{g}, \bar{g} \rangle \quad \forall \Phi^* P_K \begin{pmatrix} \bar{g} \\ g \end{pmatrix} \in \tilde{N}_e^0,
\]

which is derived in the same way as in [45] Section 7] for all \( P_K \begin{pmatrix} \bar{g} \\ g \end{pmatrix} \in \tilde{N}_e^0 \), which is equivalent to the condition \( (\bar{g} + S^*g) + (S\bar{g} + g) = 0 \), see (4.10), allows us to consider the
isometry \( F : \Phi \tilde{N}_0 \mapsto L^2(\mathcal{K}; I - S^*S) \) defined by
\[
FP_K \left( \frac{g}{\| g \|} \right) = \tilde{g}.
\] (6.1)

Here \( L^2(\mathcal{K}; I - S^*S) \) is the Hilbert space of \( \mathcal{K} \)-valued functions on \( \mathbb{R} \) square summable with the matrix “weight” \( I - S^*S \), cf. (4.2). Similarly, the formula
\[
F_*P_K \left( \frac{g}{\| g \|} \right) = g
\]
defines an isometry \( F_* \) from \( \Phi \tilde{N}_0 \) to \( L^2(\mathcal{K}; I - SS^*) \).

**Proposition 6.1** ([12]). Suppose that the assumptions of Theorem 5.3 hold. Then the ranges of the operators \( F \) and \( F_* \) are dense in the spaces \( L^2(\mathcal{K}; I - S^*S) \) and \( L^2(\mathcal{K}; I - SS^*) \), respectively.

The above statement immediately implies the next result, which allows us to obtain the required spectral representation.

**Theorem 6.2.** The operator \( F \), respectively \( F_* \), admits an extension to the unitary mapping between \( \Phi \tilde{N}_0 \) and \( L^2(\mathcal{K}; I - S^*S) \), respectively \( L^2(\mathcal{K}; I - SS^*) \).

It follows that the operator \((A_0 - z)^{-1}\) considered on \( \tilde{N}_0 \) acts as the multiplication by \((k - z)^{-1}\), \( k \in \mathbb{R} \), both in \( L^2(\mathcal{K}; I - S^*S) \) and \( L^2(\mathcal{K}; I - SS^*) \). In particular, if one considers the absolutely continuous “part” of the operator \( A_0 \), namely the operator \( A_0^{(e)} := A_0|_{N_0} \), then \( F\Phi A_0^{(e)} \Phi^*F^* \) and \( F_*\Phi A_0^{(e)} \Phi^*F_*^* \) are the operators of multiplication by the independent variable in the spaces \( L^2(\mathcal{K}; I - S^*S) \) and \( L^2(\mathcal{K}; I - SS^*) \), respectively.

In order to obtain a spectral representation from the above result, we need to diagonalise the weights in the definitions of the above \( L^2 \)-spaces. This diagonalisation is straightforward when \( \alpha = \sqrt{2}I \). (This choice of \( \alpha \) satisfies the conditions of Theorem 5.3 e.g. when the boundary space \( \mathcal{K} \) is finite-dimensional, which is the case we deal with in the application discussed in Sections 7, 8. The corresponding diagonalisation in the general setting will be treated elsewhere.) In this particular case one has (cf. (2.7))
\[
S = (M - iI)(M + iI)^{-1},
\] (6.2)
and consequently
\[
I - S^*S = -2i(M^* - iI)^{-1}(M - M^*)(M + iI)^{-1},
\] (6.3)
\[
I - SS^* = 2i(M + iI)^{-1}(M^* - M)(M^* - iI)^{-1}.
\]

Introducing the unitary transformations
\[
G : L^2(\mathcal{K}; I - S^*S) \mapsto L^2(\mathcal{K}; -2i(M - M^*)),
\] (6.4)
\[
G_* : L^2(\mathcal{K}; I - SS^*) \mapsto L^2(\mathcal{K}; -2i(M - M^*))
\] (6.5)
by the formulae \( g \mapsto (M + iI)^{-1}g \) and \( g \mapsto (M^* - iI)^{-1}g \) respectively, one arrives at the fact that \( GF\Phi A_0^{(e)} \Phi^*F^*G^* \) and \( G_*F_*\Phi A_0^{(e)} \Phi^*F_*^*G_*^* \) are the operators of multiplication.
by the independent variable in the space \( L^2(\mathcal{K}; -2i(M - M^*)) \). We show next that this amounts to the spectral representation in particular in the case of (non-compact) quantum graphs.

### 7. Quantum graphs and their scattering matrices

The result of the previous section only pertains to the absolutely continuous part of the self-adjoint operator \( A_0 \), unlike \( e.g \) the passage to the classical von Neumann direct integral, under which the whole of the self-adjoint operator gets mapped to the multiplication operator in a weighted \( L^2 \)-space (see \( e.g \) Chapter 7). Nevertheless, it proves useful in scattering theory, since it yields an explicit expression for the scattering matrix \( \hat{\Sigma} \) for the pair \( A_\mathcal{K}, A_0 \), which is the image of the scattering operator \( \Sigma \) in the spectral representation of the operator \( A_0 \). Namely, we prove the following statement.

**Theorem 7.1.** The following formula holds:

\[
\hat{\Sigma} = GF\Sigma(GF)^* = (M - \kappa)^{-1}(M^* - \kappa)(M^*)^{-1}M,
\]

where the right-hand side represents the operator of multiplication by the corresponding function.

**Proof.** Using the definition (6.1) of the isometry \( F \) along with the relationship (4.10) between \( \bar{g} \) and \( g \) whenever \( P_K(\bar{g}) \in \Phi \tilde{N}_e^\kappa \) with \( \kappa = 0 \), we obtain from (5.6):

\[
F\Sigma F^* = (I + \chi_\kappa(S - I))^{-1}(I + \chi_\kappa^+(S^* - I))(I + S^*)^{-1}(I + S),
\]

where the right-hand side represents the operator of multiplication by the corresponding function.

Furthermore, substituting the expression (2.6) for \( S \) in terms of \( M \) implies that \( F\Sigma F^* \) is the operator of multiplication by

\[
(M + iI)(M - \kappa)^{-1}(M^* - \kappa)(M^*)^{-1}M(M + iI)
\]

in the space \( L^2(\mathcal{K}; I - S^*S) \). Using (6.3), we now obtain the following identity for all \( f, g \in L^2(\mathcal{K}; I - S^*S) \):

\[
\langle F\Sigma F^*f, g \rangle_{L^2(\mathcal{K}; I - S^*S)} = \langle (I - S^*S)(M + iI)(M - \kappa)^{-1}(M^* - \kappa)(M^*)^{-1}M(M + iI)f, g \rangle
\]

\[
= \langle -2i(M^* - iI)^{-1}(M - M^*)(M + iI)^{-1}(M + iI)(M - \kappa)^{-1}(M^* - \kappa)(M^*)^{-1}M(M + iI)f, g \rangle
\]

\[
= \langle -2i(M - M^*)(M - \kappa)^{-1}(M^* - \kappa)(M^*)^{-1}M(M + iI)f, (M + iI)g \rangle,
\]

which is equivalent to (7.1), in view of the definition of the operator \( G \). \qed

In applications to quantum graphs it may turn out that the operator weight \(-2i(M - M^*)\) (see (6.4), (6.5)) is degenerate: more precisely, \( M(s) - M(s)^* = 2i\sqrt{s}P_e, s \in \mathbb{R} \), where \( P_e \) is the orthogonal projection onto the subspace of \( \mathcal{K} \) corresponding to the set of “external” vertices of the graph, \( i.e \) those vertices to which semi-infinite edges are attached. Next, we describe the notation pertaining to the quantum graph setting.
Remark 4. From this point on, for simplicity of presentation we consider the case of a finite non-compact quantum graph, when the deficiency indices are finite. However, our approach allows us to consider the general setting of infinite deficiency indices, which in the quantum graph setting leads to an infinite graph. In particular, on could consider the case of an infinite compact part of the graph.

In what follows, we denote by \( G = G(E, \sigma) \) a finite metric graph, i.e. a collection of a finite non-empty set \( E \) of compact or semi-infinite intervals \( e_j = [x_{2j-1}, x_{2j}] \) (for semi-infinite intervals we set \( x_{2j} = +\infty \), \( j = 1, 2, \ldots, n \), which we refer to as edges, and of a partition \( \sigma \) of the set of endpoints \( V := \{x_k : 1 \leq k \leq 2n, \ x_k < +\infty \} \) into \( N \) equivalence classes \( V_m, m = 1, 2, \ldots, N \), which we call vertices: \( V = \bigcup_{m=1}^{N} V_m \). The degree, or valence, \( \deg(V_m) \) of the vertex \( V_m \) is defined as the number of elements in \( V_m \), i.e. \( \text{card}(V_m) \). Further, we partition the set \( V \) into the two non-overlapping sets of internal \( V^{(i)} \) and external \( V^{(e)} \) vertices, where a vertex \( V \) is classed as internal if it is incident to no non-compact edge and external otherwise. Similarly, we partition the set of edges \( E = E^{(i)} \cup E^{(e)} \), into the collection of compact \( E^{(i)} \) and non-compact \( E^{(e)} \) edges. We assume for simplicity that the number of non-compact edges incident to any graph vertex is not greater than one.

For a finite metric graph \( G \), we consider the Hilbert spaces \( L^2(G) := \bigoplus_{j=1}^{n} L^2(e_j) \) and \( W^{2,2}(G) := \bigoplus_{j=1}^{n} W^{2,2}(e_j) \). (Notice that these spaces do not feel the graph connectivity, as each of them is the same for different graphs with the same number of edges of the same lengths.) Further, for a function \( f \in W^{2,2}(G) \), we define the normal derivative at each vertex along each of the adjacent edges, as follows:

\[
\partial_n f(x_j) := \begin{cases} 
    f'(x_j), & \text{if } x_j \text{ is the left endpoint of the edge}, \\
    -f'(x_j), & \text{if } x_j \text{ is the right endpoint of the edge}.
\end{cases}
\] (7.3)

In the case of semi-infinite edges we only apply this definition at the left endpoint of the edge.

Definition 5. For \( f \in W^{2,2}(G) \) and \( a_m \in \mathbb{C} \) (below referred to as the “coupling constant”), the condition of continuity of the function \( f \) through the vertex \( V_m \) (i.e. \( f(x_j) = f(x_k) \) if \( x_j, x_k \in V_m \)) together with the condition

\[
\sum_{x_j \in V_m} \partial_n f(x_j) = a_m f(V_m)
\]

is called the \( \delta \)-type matching at the vertex \( V_m \).

Remark 5. Note that the \( \delta \)-type matching condition in a particular case when \( a_m = 0 \) reduces to the standard Kirchhoff matching condition at the vertex \( V_m \), see e.g. [4].

Definition 6. The quantum graph Laplacian \( A_\delta, a := (a_1, \ldots, a_N) \), on a graph \( G \) with \( \delta \)-type matching conditions is the operator of minus second derivative \(-d^2/dx^2 \) in the Hilbert space \( L^2(G) \) on the domain of functions that belong to the Sobolev space \( W^{2,2}(G) \) and satisfy the \( \delta \)-type matching conditions at every vertex \( V_m, m = 1, 2, \ldots, N \). The Schrödinger operator on the same graph is defined likewise on the same domain in the case of summable edge potentials (cf. [16]).
If all coupling constants $a_m$, $m = 1, \ldots, N$, are real, it is shown that the operator $A_a$ is a proper self-adjoint extension (see (2.3)) of a closed symmetric operator $A$ in $L^2(G)$ \cite{19,34}. Note that, without loss of generality, each edge $e_j$ of the graph $G$ can be considered to be an interval $[0,l_j]$, where $l_j := x_{2j} - x_{2j-1}$, $j = 1, \ldots, n$ is the length of the corresponding edge. Throughout the present paper we will therefore only consider this situation.

In \cite{16}, the following result is obtained for the case of finite compact metric graphs.

**Proposition 7.2** (\cite{16}). Let $G$ be a finite compact metric graph with $\delta$-type coupling at all vertices. There exists a closed densely defined symmetric operator $A$ and a boundary triple such that the operator $A_a$ is an almost solvable extension of $A$, for which the parametrising matrix $\varkappa$ (see (2.3)) is given by $\varkappa = \text{diag}\{a_1, \ldots, a_N\}$, whereas the Weyl function is an $N \times N$ matrix with elements

$$
m_{jk}(z) = \begin{cases} -\sqrt{z} \left( \sum_{e_p \in E_k} \cot \sqrt{z} l_p - 2 \sum_{e_p \in L_k} \tan \frac{\sqrt{z} l_p}{2} \right), & j = k, \\
\sqrt{z} \sum_{e_p \in C_{jk}} \frac{1}{\sin \sqrt{z} l_p}, & j \neq k; \, V_j, V_k \text{ adjacent,} \\
0, & j \neq k; \, V_j, V_k \text{ non-adjacent.} 
\end{cases} \tag{7.4}
$$

Here the branch of the square root is chosen so that $\Re \sqrt{z} \geq 0$, $l_p$ is the length of the edge $e_p$, $E_k$ is the set of non-loop graph edges incident to the vertex $V_k$, $L_k$ is the set of loops at the vertex $V_k$, and $C_{jk}$ is the set of graph edges connecting vertices $V_j$ and $V_k$.

It is easily seen that the rationale of \cite{16} is applicable to the situation of non-compact metric graphs. Indeed, denote by $G^{(i)}$ the compact part of the graph $G$, i.e. the graph $G$ with all the non-compact edges removed. Proposition 7.2 yields an expression for the Weyl function $M^{(i)}$ pertaining to the graph $G^{(i)}$. A simple calculation then implies the following representation for the $M$-matrix pertaining to the original graph $G$.

**Lemma 7.3.** The matrix functions $M$, $M^{(i)}$ described above are related by the formula

$$
M(z) = M^{(i)}(z) + i\sqrt{z}P_e, \quad z \in \mathbb{C}_+ \tag{7.5}
$$

where $P_e$ is the orthogonal projection in the boundary space $K$ onto the set of external vertices $V^{(e)}_G$, i.e. the matrix $P_e$ such that $(P_e)_{ij} = 1$ if $i = j$, $V_i \in V^{(e)}_G$, and $(P_e)_{ij} = 0$ otherwise.

**Proof.** Note first that Weyl function of the graph $G$ for the triple described in Proposition 7.2 coincides with the sum of the matrices $M_j(z)$, $j = 1, 2, \ldots, n$, that are obtained by the formulae

$$
\Gamma f = M_j(z)\Gamma_0 f, \quad f \in \ker(A^* - zI), \quad f \equiv 0 \text{ on } G \setminus e_j.
$$

In order words, the matrix functions $M_j$ describe the Dirichlet-to-Neumann mappings for the data supported on each individual edge $e_j$, $j = 1, 2, \ldots, n$, where $A$ is as in Proposition 7.2.

Furthermore, functions $f \in \ker(A^* - zI)$ that vanish on all edges of the graph $G$ but one non-compact edge $e_{\infty}$, satisfy

$$
f''(x) = z f(x), \quad x \in [0, +\infty), \quad f \in W^{2,2}(0, +\infty), \tag{7.6}
$$
where we identify $e_\infty$ and the semi-infinite line $[0, +\infty)$, as well as $f$ and its restriction to $e_\infty$. Next, all non-trivial solutions to (7.6) have the form

$$f(x) = f(0) \exp(i\sqrt{z}x), \quad x \in [0, +\infty), \quad f(0) \neq 0,$$

for which the value of the co-derivative (7.3) at $x = 0$ is clearly given by $\partial_n f(0) = i\sqrt{z}f(0)$. Therefore, the corresponding (additive) contribution to the $M$-matrix, see Definition 2, is given by the matrix all of whose elements except the diagonal element corresponding to the vertex from which $e_\infty$ emanates are zero, while the only non-zero element equals $(f(0))^{-1}\partial_n f(0) = i\sqrt{z}$. Repeating this argument for all non-compact edges of $G$ and using the additivity property for the $M$-matrix discussed above yields the claim.

The formula (7.5) leads to $M(s) - M^*(s) = 2i\sqrt{z}P_e$ a.e. $s \in \mathbb{R}$, and the expression (7.1) for $\hat{\Sigma}$ leads to the classical scattering matrix $\hat{\Sigma}_e(k)$ of the pair of operators $A_0$ (which is the Laplacian on the graph $G$ with standard Kirchhoff matching at all the vertices) and $A_\kappa$, where $\kappa = \kappa = \text{diag}\{a_1, \ldots, a_N\}$:

$$\hat{\Sigma}_e(s) = P_e(M(s) - \kappa)^{-1}(M(s)^* - \kappa)(M(s)^*)^{-1}M(s)P_e, \quad s \in \mathbb{R},$$

(7.7)

which acts as the operator of multiplication in the space $L^2(P_eK; 4\sqrt{s}ds)$.

**Remark 6.** In the more common approach to the construction of scattering matrices, based on comparing the asymptotic expansions of solutions to spectral equations, see e.g. [21], one obtains $\hat{\Sigma}_e$ as the scattering matrix. Our approach yields an explicit factorisation of $\hat{\Sigma}_e$ into expressions involving the matrices $M$ and $\kappa$ only, sandwiched between two projections. (Recall that $M$ and $\kappa$ contain the information about the geometry of the graph and the coupling constants, respectively.) From the same formula (7.7), it is obvious that without the factorisation the pieces of information pertaining to the geometry of the graph and the coupling constants at the vertices are present in the final answer in an entangled form.

**Remark 7.** The concrete choice of boundary triple in accordance with Proposition 7.2 leads to the fact that the “unperturbed” operator $A_0$ is fixed as the Laplacian on the graph with Kirchhoff matching conditions at the vertices. On the other hand, in applications it may be more convenient to consider a formulation where the operator $A_0$ corresponds to some other matching conditions, which would motivate another choice of the triple. This is readily facilitated by the analysis carried out in the preceding sections, cf. Part 3 of Remark 3. In particular, we point out that the formula (7.2) is written in a triple-independent way.

We reiterate that the analysis above pertains not only to the cases when the coupling constants are real, leading to self-adjoint operators $A_a$, but also to the case of non-selfadjoint extensions, cf. Theorem 5.3.

In what follows we often drop the argument $s \in \mathbb{R}$ of the Weyl function $M$ and the scattering matrices $\hat{\Sigma}, \hat{\Sigma}_e$. Since

$$(M - \kappa)^{-1}(M^* - \kappa) = I + (M - \kappa)^{-1}(M^* - M) = I - 2i\sqrt{s}(M - \kappa)^{-1}P_e$$

(7.8)

and

$$(M^*)^{-1}M = I + 2i\sqrt{s}(M^*)^{-1}P_e,$$
a factorisation of $\hat{\Sigma}_e$ into a product of $\varkappa$–dependent and $\varkappa$–independent factors (cf. [7.1]) still holds in this case in $P_e \mathcal{K}$, namely

$$\hat{\Sigma}_e = [P_e(M - \varkappa)^{-1}(M^* - \varkappa)] [P_e(M^*)^{-1}MP_e]. \quad (7.9)$$

8. Inverse scattering problem for graphs with $\delta$-coupling

We will now exploit the above approach in the analysis of the inverse scattering problem for Laplace operators on finite metric graphs, whereby the scattering matrix $\hat{\Sigma}_e(s)$, defined by (7.9), is assumed to be known for almost all positive “energies” $s \in \mathbb{R}$, along with the graph $\hat{G}$ itself. The data to be determined is the set of coupling constants $\{a_j\}_{j=1}^N$. For simplicity, in what follows we treat the inverse problem for graphs with real coupling constants, which corresponds to self-adjoint operators, leaving the non-self-adjoint situation to be addressed elsewhere.

First, given $\hat{\Sigma}_e(s)$ for almost all $s > 0$, we reconstruct the meromorphic matrix-function $P_e(M^{(i)}(z) - \varkappa)^{-1}P_e$ for all complex $z$, excluding the poles. This is an explicit calculation based on the second resolvent identity (see e.g. [65, Thm. 5.13]). Namely, almost everywhere on the positive half-line one has

$$(M - \varkappa)^{-1} = (M^{(i)} - \varkappa)^{-1} - (M - \varkappa)^{-1} (M - M^{(i)})(M^{(i)} - \varkappa)^{-1}$$

$$= [I - (M - \varkappa)^{-1} (M - M^{(i)})] (M^{(i)} - \varkappa)^{-1},$$

and hence

$$P_e(M - \varkappa)^{-1}P_e = [P_e - i\sqrt{s}P_e (M - \varkappa)^{-1}P_e] P_e(M^{(i)} - \varkappa)^{-1}P_e. \quad (8.1)$$

Further, the first factor on the right-hand side of (8.1) is invertible for almost all $s > 0$. Indeed, we note first that $\hat{\Sigma}_e^{\varkappa} := P_e(M(s) - \varkappa)^{-1}(M(s)^* - \varkappa)$ is unitary in $P_e \mathcal{K}$ for almost all $s > 0$, since

$$(M - \varkappa)(M^* - \varkappa)^{-1}(M - M^*) (M - \varkappa)^{-1} (M^* - \varkappa)$$

$$= (M - \varkappa)(M^* - \varkappa)^{-1} [(M - \varkappa) - (M^* - \varkappa)] (M - \varkappa)^{-1} (M^* - \varkappa)$$

$$= (M - \varkappa) - (M^* - \varkappa) = M - M^*$$

and $M - M^* = 2i\sqrt{s}P_e$. Now, since

$$P_e - i\sqrt{s}P_e (M - \varkappa)^{-1}P_e = (I + \hat{\Sigma}_e^{\varkappa})/2$$

it suffices to show that $-1$ is not an eigenvalue of $\hat{\Sigma}_e^{\varkappa}(s)$ for almost all $s > 0$. Assume the opposite, i.e. for some $s > 0$ one has

$$(M(s)^* - \varkappa)^{-1}u_s = -(M(s) - \varkappa)^{-1}u_s, \quad u_s \in P_e \mathcal{K} \setminus \{0\}.$$

A straightforward calculation then yields

$$(M(s)^* - \varkappa)^{-1}(M^{(i)}(s) - \varkappa)(M(s) - \varkappa)^{-1}u_s = 0,$$
from where

\[(M(s) - \varkappa)^{-1} u_s \in \ker((M^{(i)})'(s) - \varkappa).\]

The latter kernel is non-trivial only at the points \(s\) which belong to the (discrete) spectrum of the Laplacian on the compact part \(\mathcal{G}^{(i)}\) of the graph \(\mathcal{G}\). It follows that \((M(s) - \varkappa)^{-1} u_s\) is zero for almost all \(s > 0\), which is a contradiction with \(u_s \neq 0\).

Note that, for a given graph \(\mathcal{G}\), the expression \(P_0(M - \varkappa)^{-1} P_e\) is found by combining (7.8) and (7.9):

\[
P_0(M - \varkappa)^{-1} P_e = \frac{1}{2i\sqrt{s}} \left( P_e - \hat{\Sigma}_e [P_e(M^*)^{-1}MP_e]^{-1} \right), \tag{8.2}
\]

where we treat both \([P_e(M^*)^{-1}MP_e]^{-1}\) and, as before, \(\hat{\Sigma}_e\) as operators in \(P_0 \mathcal{K}\).

It follows from (8.1) and (8.2) that for given \(M, \hat{\Sigma}_e\) the expression \(P_0(M^{(i)} - \varkappa)^{-1} P_e\) is determined uniquely for almost all \(s > 0\):

\[
P_0(M^{(i)} - \varkappa)^{-1} P_e = \left[ P_e - i\sqrt{s} P_e(M - \varkappa)^{-1} P_e \right]^{-1} P_e(M - \varkappa)^{-1} P_e
= \frac{1}{i\sqrt{s}} \left( P_e + \hat{\Sigma}_e [P_e(M^*)^{-1}MP_e]^{-1} \right)^{-1} \left( P_e - \hat{\Sigma}_e [P_e(M^*)^{-1}MP_e]^{-1} \right)
= \frac{1}{i\sqrt{s}} \left( 2(P_e + \hat{\Sigma}_e [P_e(M^*)^{-1}MP_e]^{-1}) - I \right) P_e, \tag{8.3}
\]

In particular, due to the property of analytic continuation, the expression \(P_0(M^{(i)} - \varkappa)^{-1} P_e\) is determined uniquely in the whole of \(\mathbb{C}\) with the exception of a countable set of poles, which coincides with the set of eigenvalues of the self-adjoint Laplacian \(A^{(i)}_\varkappa\) on the compact part \(\mathcal{G}^{(i)}\) of the graph \(\mathcal{G}\) with matching conditions at the graph vertices given by the matrix \(\varkappa\), cf. Proposition 7.2.

**Definition 7.** Given a partition \(\mathcal{V}_1 \cup \mathcal{V}_2\) of the set of graph vertices, for \(z \in \mathbb{C}\) consider the linear set \(U(z)\) of functions that satisfy the differential equation \(-u''_z = zu_z\) on each edge, subject to the conditions of continuity at all vertices of the graph and the \(\delta\)-type matching conditions at the vertices in the set \(\mathcal{V}_2\). For each function \(f \in U(z)\), consider the vectors

\[
\Gamma^{\mathcal{V}_1}_1 u_z := \left\{ \sum_{x_j \in V_m} \partial_n f(x_j) \right\}_{V_m \in \mathcal{V}_1}, \quad \Gamma^{\mathcal{V}_1}_0 u_z := \left\{ f(V_m) \right\}_{V_m \in \mathcal{V}_1}.
\]

The *Robin-to-Dirichlet map* of the set \(\mathcal{V}_1\) maps the vector \((\Gamma^{\mathcal{V}_1}_1 - \varkappa^{\mathcal{V}_1}_1 \Gamma^{\mathcal{V}_1}_0) u_z\) to \(\Gamma^{\mathcal{V}_1}_0 u_z\), where \(\varkappa^{\mathcal{V}_1}_1 := \text{diag}\{a_m : V_m \in \mathcal{V}_1\}\). (Note that the function \(u_z \in U(z)\) is determined uniquely by \((\Gamma^{\mathcal{V}_1}_1 - \varkappa^{\mathcal{V}_1}_1 \Gamma^{\mathcal{V}_1}_0) u_z\) for all \(z \in \mathbb{C}\) except a countable set of real points accumulating to infinity).

**Remark 8.** The above definition is a natural generalisation of the corresponding definitions of Dirichlet-to-Neumann and Neumann-to-Dirichlet maps pertaining to the graph boundary, considered in e.g. [4], [39].

We argue that the matrix \(P_0(M^{(i)} - \varkappa)^{-1} P_e\) is the Robin-to-Dirichlet map for the set \(\mathcal{V}^{(e)}\). Indeed, assuming \(\phi := \Gamma_1 u_z - \varkappa \Gamma_0 u_z\) and \(\phi = P_0 \phi\), where the latter condition ensures the correct \(\delta\)-type matching on the set \(\mathcal{V}^{(i)}\), one has \(P_0 \phi = (M^{(i)} - \varkappa) \Gamma_0 u_z\) and
hence $\Gamma_0 u_\omega = (M^{(i)} - \omega)^{-1} P e \phi$. Applying $P e$ to the last identity yields the claim, in accordance with Definition 7.

We have thus proved the following theorem.

**Theorem 8.1.** The Robin-to-Dirichlet map for the vertices $V^{(e)}$ is determined uniquely by the scattering matrix $\hat{\Sigma}_e(s)$, $s \in \mathbb{R}$, via the formula (8.3).

The following definition, required for the formulation of the next theorem, is a generalisation of the procedure of graph contraction, well studied in the algebraic graph theory, see e.g. [61].

**Definition 8** (Contraction procedure for graphs and associated quantum graph Laplacians). For a given graph $G$ vertices $V$ and $W$ connected by an edge $e$ are “glued” together to form a new vertex $(VW)$ of the contracted graph $\hat{G}$ while simultaneously the edge $e$ is removed, whereas the rest of the graph remains unchanged. We do allow the situation of multiple edges, when $V$ and $W$ are connected in $G$ by more than one edge, in which case all such edges but the edge $e$ become loops of their respective lengths attached to the vertex $(VW)$. The corresponding quantum graph Laplacian $A_a$ defined on $G$ is contracted to the quantum graph Laplacian $\hat{A}_{\hat{a}}$ by the application of the following rule pertaining to the coupling constants: a coupling constant at any unaffected vertex remains the same, whereas the coupling constant at the new vertex $(VW)$ is set to be the sum of the coupling constants at $V$ and $W$. Here it is always assumed that all quantum graph Laplacians are described by Definition 6.

The matrix $\omega$ of the coupling constants is now determined as part of an iterative procedure based on the following result.

**Theorem 8.2.** Suppose that the edge lengths of the graph $G^{(i)}$ are rationally independent. The element $(1,1)$ of the Robin-to-Dirichlet map described above yields the element $(1,1)$ of the “contracted” graph $\hat{G}^{(i)}$ obtained from the graph $G^{(i)}$ by removing a non-loop edge $e$ emanating from $V_1$. The procedure of passing from the graph $G^{(i)}$ to the contracted graph $\hat{G}^{(i)}$ is given in Definition 8.

**Proof.** Due to the assumption that the edge lengths of the graph $G^{(i)}$ are rationally independent, the element $(1,1)$, which we denote by $f_1$, is expressed explicitly as a function of $\sqrt{\omega} \text{ and all the edge lengths } l_j, j = 1, 2, \ldots, n, \text{ in particular, of the length of the edge } e, \text{ which we assume to be } l_1 \text{ without loss of generality. This is an immediate consequence of the explicit form of the matrix } M^{(i)}, \text{ see (7.4). Again without loss of generality, we also assume that the edge } e \text{ connects the vertices } V_1 \text{ and } V_2.$

Further, consider the expression $\lim_{l_1 \to 0} f_1(\sqrt{\omega}; l_1, \ldots, l_n; a)$. On the one hand, this limit is known from the explicit expression for $f_1$ mentioned above. On the other hand, $f_1$ is the ratio of the determinant $D^{(1)}(\sqrt{\omega}; l_1, \ldots, l_n; a)$ of the principal minor of the matrix $M^{(i)}(\omega) - \omega$ obtained by removing its first row and and first column and the determinant of $M^{(i)}(\omega) - \omega$ itself:

$$f_1(\sqrt{\omega}; l_1, \ldots, l_n; a) = \frac{D^{(1)}(\sqrt{\omega}; l_1, \ldots, l_n; a)}{\det(M^{(i)}(\omega) - \omega)}$$

One of the referees pointed out that this procedure is sometimes referred to a “layer peeling”. We have opted to keep the term “contraction” for it, in line with the terminology of the algebraic literature.

By renumbering if necessary, this does not lead to loss of generality.
Next, we multiply by \(-l_1\) both the numerator and denominator of this ratio, and pass to the limit in each of them separately:

\[
\lim_{l_1 \to 0} f_1(\sqrt{z}; l_1, \ldots, l_n; a) = \frac{\lim_{l_1 \to 0} (-l_1)D^{(1)}(\sqrt{z}; l_1, \ldots, l_n; a)}{\lim_{l_1 \to 0} (-l_1)\det(M^{(i)}(z) - \infty)}
\] (8.4)

The numerator of (8.4) is easily computed as the determinant \(D^{(2)}(z; l_1, \ldots, l_n; a)\) of the minor of \(M^{(i)}(z) - \infty\) obtained by removing its first two rows and first two columns.

As for the denominator of (8.4), we add to the second row of the matrix \(M^{(i)}(z) - \infty\) its first row multiplied by \(\cos(\sqrt{z}l_1)\), which leaves the determinant unchanged. This operation, due to the identity

\[- \cot(\sqrt{z}l_1)\cos(\sqrt{z}l_1) + \frac{1}{\sin(\sqrt{z}l_1)} = \sin(\sqrt{z}l_1),\]

cancels out the singularity of all matrix elements of the second row at the point \(l_1 = 0\). We introduce the factor \(-l_1\) (cf. 8.4) into the first row and pass to the limit as \(l_1 \to 0\). Clearly, all rows but the first are regular at \(l_1 = 0\) and hence converge to their limits as \(l_1 \to 0\). Finally, we add to the second column of the limit its first column, which again does not affect the determinant, and note that the first row of the resulting matrix has one non-zero entry (1,1) entry. This procedure reduces the denominator in (8.4) to the determinant, and note that the first row of the resulting matrix has one non-zero element, namely the (1,1) entry. This procedure reduces the denominator in (8.4) to the determinant of a matrix of the size reduced by one. As in [17], it is checked that this determinant is nothing but \(\det(\tilde{M}^{(i)} - \tilde{\nu})\), where \(\tilde{M}^{(i)}\) and \(\tilde{\nu}\) are the Weyl matrix and the (diagonal) matrix of coupling constants pertaining to the contracted graph \(\tilde{G}^{(i)}\). This immediately implies that the ratio obtained as a result of the above procedure coincides with the entry (1,1) of the matrix \((\tilde{M}^{(i)} - \tilde{\nu})^{-1}\), i.e.

\[
\lim_{l_1 \to 0} f_1(\sqrt{z}; l_1, \ldots, l_n; a) = f_1^{(1)}(\sqrt{z}; l_2, \ldots, l_n; \tilde{a}),
\] (8.5)

where \(f_1^{(1)}\) is the element (1,1) of the Robin-to-Dirichlet map of the contracted graph \(\tilde{G}^{(i)}\), and \(\tilde{a}\) is given by Definition 8.

The main result of this section is the theorem below, which is a corollary of Theorems 8.1 and 8.2. We assume without loss of generality that \(V_1 \in \mathcal{V}^{(\varepsilon)}\) and denote by \(f_1(\sqrt{z})\) the (1,1)-entry of the Robin-to-Dirichlet map for the set \(\mathcal{V}^{(\varepsilon)}\). We set the following notation. Fix a spanning tree \(\mathcal{T}\) (see e.g. [61]) of the graph \(G^{(i)}\). We let the vertex \(V_1\) to be the root of \(\mathcal{T}\) and assume, again without loss of generality, that the number of edges in the path \(\gamma_m\) connecting \(V_m\) and the root is a non-decreasing function of \(m\). Denote by \(N^{(m)}\) the number of vertices in the path \(\gamma_m\), and by \(\{l_k^{(m)}\}, k = 1, \ldots, N^{(m)} - 1\), the associated sequence of lengths of the edges in \(\gamma_m\), ordered along the path from the root \(V_1\) to \(V_m\). Note that each of the lengths \(l_k^{(m)}\) is clearly one of the edge lengths \(l_j\) of the compact part of the original graph \(G\).

**Theorem 8.3.** Assume that the graph \(G\) is connected and the lengths of its compact edges are rationally independent. Given the scattering matrix \(\Sigma_\varepsilon(s), s \in \mathbb{R}\), the Robin-to-Dirichlet map for the set \(\mathcal{V}^{(\varepsilon)}\) and the matrix of coupling constants \(\nu\) are determined
the coupling constant \( a \) where

\[ \tilde{\text{vertex}} \rightarrow \text{map for the set } V \]

We first apply Theorem 8.1 to determine the Robin-to-Dirichlet map for the vertices

\[ \text{Proof.} \]

where in the case \( l = 1 \) no limits are taken in (8.6).

\[ f_1^{(l)}(\sqrt{z}) := \lim_{\rho^{(l)}_{N(i) \rightarrow 0} \rho^{(l)}_{2} \rightarrow 0} \lim_{\rho^{(l)}_{1} \rightarrow 0} f_1(\sqrt{z}), \quad (8.6) \]

where the first sum in (8.7) is taken over all non-loop edges \( e_p \) of \( G^{(1)} \) emanating from the vertex \( V_1 \) and the second over all loops \( l_p \) attached to \( V_1 \). The coupling constant \( a_1 \) is then recovered directly from (8.8).

In order to determine the coupling constant \( a_2 \), we apply Theorem 8.2. In order to do so we note that the the vertex \( V_2 \) is connected to \( V_1 \) by the edge of the length \( f_1^{(2)} \) and apply the contraction procedure along this edge. In particular, the formula (8.5), together with asymptotics (8.8) re-written for the first diagonal element of the contracted graph, yields the coupling constant pertaining to the vertex \( \tilde{V}_1 := (V_1V_2) \) of the contracted graph, which, by Theorem 8.2, is equal to \( a_1 + a_2 \):

\[ a_1 + a_2 = \lim_{\tau \rightarrow +\infty} \left\{ i\tau \left( - \sum_{e_p \in \tilde{E}_1} \cot(i\tau l_p) + 2 \sum_{e_p \in \tilde{L}_1} \tan(i\tau l_p/2) \right) - \frac{1}{f_1^{(1)}} \right\} \]

\[ = \lim_{\tau \rightarrow +\infty} \left\{ -\tau \left( \deg(V_1) + \deg(V_2) - 2 \right) - \frac{1}{f_1^{(1)}} \right\}, \quad (8.9) \]

where \( \tilde{E}_1 \) is the set of all non-loop edges of the contracted graph \( \tilde{G}^{(1)} \) emanating from the vertex \( \tilde{V}_1 \), \( \tilde{L}_1 \) is the set of loops attached to this same vertex, and \( f_1^{(1)} \), explicitly given by (8.5), is the element (1,1) of the Robin-to-Dirichlet map of the contracted graph. Thus we recover the value of the coupling constant \( a_2 \), as a result of consequent evaluations of indeterminate forms of two different types: “0/0” (see (8.5)) and “\( \infty - \infty \)” (see (8.9)).

Since the graph \( G \) is connected, the above procedure is iterated until the only remaining vertex of the contracted graph is \( V_1 \), at which point the last coupling constant \( a_N \) is
determined. The claim of the theorem follows.

**Remark 9.** 1. Notice that each step of the above iterative process generates a set of loops, which is treated according to the formula \([8.7]\). Alternatively, these loops can be discarded by an elementary recalculation of the corresponding element of the Robin-to-Dirichlet map in the application of Theorem \([8.2]\).

2. From the proof of Theorem \([8.3]\) it actually follows that the inverse problem of determining matching conditions based on the Robin-to-Dirichlet map pertaining to any subset of graph vertices for any finite and compact graph \(G\) has a unique and constructive solution. As in the theorem, the graph is assumed connected and its edge lengths rationally independent. More than that, for the solution of the named inverse problem it suffices to know any one diagonal element of the Robin-to-Dirichlet map.
