SYNOPSIS

Transition metal catalysed carbon-carbon bond forming reactions are central to the synthesis of many biologically interesting molecules. Amongst the many catalytic transformations the rhodium-catalysed addition reaction has seen a recent rise in popularity; this is due to the broad applicability of the chemistry to a range of substrates with a variety of functional groups. Many substrates are able to perform both 1,4- and 1,2-additions and the mechanism by which this occurs has been well documented. However there are still many substrates available by which to extend the scope of these reactions and questions as to what effects these new substrates may have on the current ideas of the mechanism and the accepted origin of enantioselectivity.

This thesis describes the exploration of rhodium catalysed addition reactions with organoboranes encompassing a synthesis of simple arylketones and the 1,4-addition to dialkyl itaconic esters.

The first chapter reviews rhodium catalysed additions through the application of a range of organoboranes. This includes a detailed discussion on the accepted mechanism and highlights some of the more unusual outcomes as well as the more established 1,4- and 1,2-addition products.

Chapter two describes the discovery of a new methodology for the synthesis of simple ketones. This method successfully exploits the rhodium/boron transmetallation process to achieve a highly versatile procedure which is not hindered by the characteristic functional groups restrictions of Friedel Crafts reactions.

The third chapter establishes the 1,4-addition of organoboronic acids to dimethyl succinates. This is primarily achieved, racemically, in water and then, through the exploration of many parameters, asymmetrically in organic solvents. This study highlights the fact that when dealing with 1,1-disubstituted activated alkenes it is more difficult to produce enantioselective results as the chirality is determined is in the protonation step and not during insertion.
I would first like to thank Dr. Chris Frost for his enthusiasm, patience and encouragement throughout my PhD. I thoroughly enjoyed my time working for you.

I am grateful to all the technical staff at the University of Bath for the analysis of my compounds and their general assistance.

My thanks to my three proof readers – Chris, Steve and Diane.

I would also like to thank all members of Frost group both past and present but especially Chris Chapman who was not only an excellent person to work along side and bounce ideas off but became a true friend through the years.

Diane also deserves a special mention for being an excellent friend providing wine and encouragement in equal measures. You made working upstairs a lot of fun and I am very grateful for your support.

I feel incredibly lucky to have gained many wonderful friends throughout my time as a postgraduate. To mention them briefly does not do them justice but cheers to Fran, Steve F. (and Diane & Alex), Steve H. (and Jen), Joe, Cath, Duncan, Dave, Phil P., Phil B., Helen, Marcus, and last but by no means least Gareth B.

To my family for your encouragement, inspiration and support since I first uttered the words “I wanna be a scientist” (how I’m sure you wish I had said hairdresser).

To Jules, for always being there.

And finally, my Ali. Who has cheered me on from the side lines and picked me up when I fell down. I have put you through so much in these last few months and you’ve loved me all the same. I could not have asked for more in a husband, nor could I love you more.

To all of you,

Thank You

Chapter Two

Rhodium-Catalysed Acylations

1 LITERATURE REVIEW OF RHODIUM-CATALYSED ADDITIONS OF ORGANOBORANES

1.1 INTRODUCTION

Carbon-carbon (C-C) bond forming reactions are of the utmost importance to the organic chemists. This is reflected by the continued high level of research and growing number of methods available to perform this operation. Transition metals in particular are increasingly being employed as catalysts for these reactions with palladium principally being utilised. Palladium catalysts can perform a whole range of versatile reactions including Kumada-Corriu,1 Mirozoki-Heck,2 Stille,3 and Suzuki-Miyaura4 coupling reactions which permit the cross-coupling of a range of substrates.

One of the most important carbon-carbon bond forming reactions is the conjugate addition to alkenes. The use of metal catalysts in combination with organometallic reagents has been particularly effective producing products in high yield and enantioselectivity. Metals used to catalyse these reactions include copper,5 rhodium,6,7 zinc, and palladiums while the organometallics applied include Grignard, organozinc and organolithium reagents.

Recently rhodium, in combination with organoboranes, has seen increasing application in this area with the catalytic systems possessing new and complementary reactivity to previously used catalyst systems. Rhodium has the added advantage over other metals, from an environmental perspective, as water can be used as a co-solvent and even the sole solvent in number of reactions. In addition the use of organoboranes is advantageous due to their low toxicity, high tolerance for functional groups and relatively high level of stability in air.

This chapter will provide an overview of rhodium-catalysed carbon-carbon bond forming reactions using organoboranes.
1.2 1,4-CONJUGATE ADDITION

1.2.1 Additions To Enones

Miyaura and co-workers first published the rhodium-catalysed 1,4-addition of aryl- and alkenyl-boronic acids to enones in 1997.\(^8\) This initial report obtained the addition products in high yields with the combination of [Rh(acac)(CO)\(_2\)] and dppb as the catalyst in methanol/H\(_2\)O (6/1) at 50°C. The quantity of water present is a significant factor in achieving a high yield since too much water leads to the hydrolysis of the boronic acid, however, no reaction occurs in the absence of water. A range of bis(phosphine) ligands were examined, the results of which indicated that as the P-Rh-P angle (bite angle) increased the rate of reaction also increased. This led to the series dppb>dppp>TFP>dppe, PPh\(_3\) & AsPh\(_3\). This effect is more pronounced when using the less reactive 2-octen-4-one as the substrate. Methyl vinyl ketone 1 on the other hand, gave excellent yields for all ligands (Scheme 1). No appreciable difference was noted for electron-withdrawing or donating groups on the boronic acid, although sterically hindered boronic acids such as 2-methoxyphenylboronic acid required extended reaction times and two equivalents of boronic acids to achieve a significant yield.

![Scheme 1](attachment:scheme_1.png)

These conditions were then modified to include the asymmetric 1,4 addition of boronic acids.\(^9\) Most significant was the change in catalyst to [Rh(acac)(C\(_2\)H\(_4\))\(_2\)], which formed the chiral rhodium-BINAP complex instantly when stirred with the chiral phosphine ligand. The co-ordination of BINAP with [Rh(acac)(CO)\(_2\)] was much slower and led to a mixture of catalysts being formed, the components of
which were not investigated further. For the addition to cyclohexenone an increase in temperature (100°C) and a change in solvent (dioxane/water (10/1)) led to a 64% yield of (S)-3-phenylcyclohexanone 2 with a 97% enantioselectivity after only 5 hours (Scheme 2). The elevated temperature led to an increased hydrolysis of phenyl boronic acid thus between 1.4 and 5 equivalents of boronic acid were required to achieve a reasonable yield. A wide variety of electron-deficient and electron-rich boronic acids were tolerated with linear as well as cyclic enones proving successful.

\[

\]

\[
\text{97% ee}
\]

Scheme 2

Although BINAP was used very successful as the first chiral ligand to be applied to the 1,4-addition to cyclohexenone, a vast range of ligands have since been employed with varying success (Scheme 3). High yields are obtained for chelating bisphosphine ligands such as DIOP 5 and Chiraphos 8 but these do not compete enantioselectively.\textsuperscript{10} Monodentate phosphines (MeO-MOP) 9, and phosphines containing an oxazoline (ip-phox) 11 or an amino group (bppfa) 10 all performed disappointingly with low yields and ee's. Amidomonophosphine 7, a ligand derived from L-proline, gave comparable enantioselectivity through a hemi-labile mechanism. The chelating ability of this ligand proved crucial as other derivatives that had poorer chelating ability resulted in a lower ee.\textsuperscript{11} Using identical conditions Reetz proposed 1,1'-binaphthol-based diphosphonites 12 which are strongly dependent on the achiral backbone for their selectivity.\textsuperscript{12} These ligands performed well giving high ees from a much lower catalyst loading. Chelating dienes such as the norbornadiene based ligand 6 also performed extremely well with 94% yield and 96% ee.
More recently, Feringa and co-workers have shown phosphoramidite 13 (MonoPhos) (Scheme 4) to be successful in the addition of phenylboronic acid 2 to cyclohexenone 3 affording the desired product 4 with 100% conversion and 84% ee when used in combination with \([\text{Rh} (\text{acac})(\text{C}_2\text{H}_4)_2]\) in dioxane/water at 100°C.\textsuperscript{13} Miyaura also demonstrated that at 50°C the same high selectivity and reactivity can be obtained, if potassium hydroxide is added to the reaction mixture, producing 3-
phenylcyclohexenone 3 in 95% yield and 98% enantiopurity.\textsuperscript{14} Feringa expanded on this by synthesising and investigating a range of phosphoramidites.\textsuperscript{15} Phosphoramidite 15 proved most successful with catalyst loading being able to be reduced to only 0.05 mol\% with no loss in yield or enantioselectivity. When compared directly to BINAP it was shown that phosphoramidite 15 reached full conversion after 10 minutes, whereas BINAP had only reached 20% conversion. Contrary to standard observations enantioselectivity was not temperature dependent and high selectivity (>94\% ee) was seen for temperatures in the range of 45°C-140°C.

\begin{equation}
\text{[Rh(acac)(C_2H_4)_2]/ligand} \\
dioxane/H_2O (10/1), 100°C
\end{equation}

\begin{align*}
L = 13 & \quad 84\% \text{ ee} \\
L = 14 & \quad 89\% \text{ ee} \\
L = 15 & \quad >98\% \text{ ee}
\end{align*}

\begin{equation}
13 \quad R^1 = R^2 = \text{Me} \\
14 \quad R^1 = R^2 = \text{Me} \\
15 \quad R^1 = R^2 = \text{Et}
\end{equation}

\textbf{Scheme 4}

The water soluble ligand, (R)-digm-BINAP 16, encompasses a BINAP skeleton as a basic structure and contains two guanidinium salts on the binaphthyl, has been utilised by Michlet and Genet in the rhodium-catalysed 1,4-addition.\textsuperscript{16} Although this catalyst system fails when water is used as the only solvent, phenylation of 2-cyclohexenone 3 efficiently occurs in ethylene glycol in the presence of sodium carbonate with catalyst loadings as low as 0.005\% and proceeds with high yields and enantioselectivity (Scheme 5).
Rhodium-catalysed conjugate additions have been applied to natural product synthesis such as (-)-(R)-Baclofen ((R)-4-amino-3-(4-chlorophenyl)-butyric acid) \textsuperscript{17} and other GABA analogues such as (-)-(R)-Rolipram (4-(3-cyclopentyl-4-methoxyphenyl)pyrrolidin-2-one) \textsuperscript{18} (Scheme 6).

Helmchen\textsuperscript{17,18} demonstrated that when \(\alpha,\beta\)-unsaturated \(\gamma\)-amino-butyric acid ester \textsuperscript{19} is treated with 4-chlorophenylboronic acid \textsuperscript{20} in the presence of \([\text{Rh(acac})(\text{C}_2\text{H}_4)_2]/(S)-\text{BINAP}\) with cesium carbonate as base in dioxane/water (10/1) at 100°C protected \(\gamma\)-amino-butyric acid \textsuperscript{21} is produced in 96% yield and 87% ee.
Chapter Two

Rhodium-Catalysed Acylations

(Scheme 7). This product 21 was then further reacted to afford Baclofen 17 in just two more steps. Similarly, Rolipram 18 is synthesised through the use of boronic acid 22. In fact a number of Boronic acids proved successful in providing an array of derivatives of both these GABA analogues.

![Scheme 7](image)

C-Glycosides possess potent antibacterial, antiviral and antitumor activities. Maddaford demonstrated that they could be efficiently prepared through rhodium-catalysed 1,4-addition of arylboronic acids to enones derived from glycols (Scheme 8).\(^{19}\) This reaction proved to be stereoselective for the α-anomer and is highly dependent on the nature of the rhodium catalyst. For example \([\text{Rh}(\text{acac})(\text{C}_2\text{H}_4)_2]\) in the presence of phosphine ligands failed to yield any of the desired 1,4-addition product. However, when \([\text{Rh(COD)}_2][\text{BF}_4]\) is heated to 100°C with phenylboronic acid and 24 in dioxane/water (20/1) 76% of 25 was obtained after 4 hours. \(^1\text{H}\) and \(^{13}\text{C}\) NMR revealed the presence of a single anomer for all products, which were assigned the α-configuration by comparison with known products. A variety of boronic acids were effectively coupled and identified in this fashion in moderate to high yields.
Chapter Two

Rhodium-Catalysed Acylations

Scheme 8

In all of the previous examples, the product has been obtained via hydrolysis of the boron intermediate. However, Hayashi proposed that the boron enolate intermediate 26 would be a more useful product which could be hydrolysed or manipulated as desired to give a range of products, examples of which are shown in Scheme 9.

Scheme 9

2-Cyclohexenone 3 reacts with 1.1 equivalents of $\beta$-Ph-9BBN 29 in the presence of 3mol% $[\text{Rh(OMe)(COD)}]_2/(S)$-BINAP in anhydrous toluene at 80°C for 1 hour to give product 26 in high yield and 98% ee.
Additions of Potassium Trifluoroborates

Potassium trifluoroborates are known to be a more stable alternative to boronic acids, making them a favourable choice for addition reactions in aqueous solutions. Batey et al. demonstrating their use under Miyuari’s original conditions of \([\text{Rh(acac)}(\text{CO})_2] \) with dpbb in methanol/water at 50°C (Scheme 10).\(^{20}\) This proved successful and the enhanced stability and increased reactivity led to a broader range of aryl and alkenyl groups being successfully coupled under milder conditions.

\[
\begin{align*}
\text{MeOH/H}_2\text{O}, 50^\circ\text{C, 16h} \\
\begin{array}{c}
\text{[Rh(acac)}(\text{CO})_2]/\text{dpbb} \\
\text{PhB(OH)}_2 = 82\% \text{ yield} \\
\text{PhBF}_3\text{K} = 91\% \text{ yield}
\end{array}
\end{align*}
\]

Scheme 10

Genet found that cationic rhodium catalyst \([\text{Rh(COD)}_2][\text{PF}_6] \) performed better in combination with trifluoroborates. In the presence of a rhodium catalyst generated from \([\text{Rh(COD)}_2][\text{PF}_6] \) and \((R)-\text{BINAP} \) in toluene/water (4/1), the addition of vinyl trifluoroborate to 2-cyclohexenone proceeded at 105-110°C to give a high yield of vinylation product 30 with 98%ee.

\[
\begin{align*}
\text{toluene/H}_2\text{O (4/1)} \\
\text{reflux, 1h} \\
\text{83% yield} \\
\text{98% ee}
\end{align*}
\]

Scheme 11

Interestingly, the reactions of potassium organotrifluoroborates have some characteristic features that differ from those of the organoboronic acids. Such as the fact that their reactions display a low reactivity when catalysed by complexes generated from neutral rhodium sources such as \([\text{Rh(acac)}(\text{C}_2\text{H}_4)_2] \), and the enantioselectivity obtained is highly dependent on the bulk solvent employed. The
use of toluene as co-solvent and an excess amount of water was found to be important for a high enantioselectivity. It is remarkable that an unsubstituted vinyl group can be introduced in a high yield by use of vinyl trifluoroborate 31; the corresponding vinyl boronic acid cannot be used due to its instability under the reaction conditions (Scheme 11). Genet and co-workers, have also examined several other chiral bisphosphines for the reaction of phenyltrifluoroborate with cyclohexenone (Scheme 12). The highest enantioselectivities were observed with (R)-(S)-Josiphos 32 (99%ee) and (R)-MeO-Biphep 33 (98%ee), whilst the lowest were obtained with the less bulky (R,R)-DIOP 35 (26%ee) and (R,R)-Dipamp 34 (3%ee).

Scheme 12
1.2.2 One-Pot Reactions: Organoborane Formation and 1,4-additions

Alkenylcatecholboranes are obtained by the hydroboration of alkynes with catecholborane (Scheme 13). Hayashi demonstrated their use in asymmetric 1,4-addition to cyclohexenone. In the presence of 3 mol% [Rh(acac)(C₂H₄)₂]/BINAP and triethylamine in dioxane/H₂O (10/1) at 100°C, the reaction of (E)-1-heptenylborane 35 with cyclohexenone 3 produced 92% of the addition product 36 in 96% enantiomeric purity. The addition of base is required to neutralise the acidic conditions formed by the hydrolysis of the alkenylcatecholborane, in the absence of base the yield was only 27%.

![Scheme 13](image)

This reaction was proven to be successful in a one-pot process, with the in situ formation of the boron intermediate. These conditions were then applied to a variety of alkynes and enones using five equivalents of borane and two equivalents of triethylamine resulting in high yields and enantioselectivities (Scheme 14).
Another one-pot synthesis demonstrated by Hayashi uses lithium trimethylborates, readily generated from treatment of aryl bromides with butyl lithium and trimethoxyborane (Scheme 15). Although no additional base was required the amount of water present greatly affected the yield, however the enantioselectivity remained undisturbed. Optimum yields were obtained with one equivalent of water to cyclohexenone. These lithium trimethylborates proved superior to boronic acids in both yield and enantioselectivity over a range of substrates.

The main advantage of both of these routes is that there is no need to isolate the boron reagent formed.

### 1.2.3 Additions to α,β-Unsaturated Esters

α,β-Unsaturated esters have proven to be less reactive than their ketone counterparts requiring higher temperatures and are more sensitive to steric bulk when applied to
rhodium-catalysed 1,4-additions. For example, ($E$)-methyl hex-2-enoate 37 reacted with phenylboronic acid in the presence of $[\text{Rh}(\text{acac})(\text{C}_2\text{H}_4)_2]/\text{BINAP}$ in dioxane/water (10/1) at 100°C to generate the addition product 38 in 94% yield and 86% ee (Scheme 16). However, when the methyl ester is replaced by a 'Bu the yield drops dramatically to 21%. This is attributed to the phenylboronic acid being consumed by hydrolysis before the reaction is complete. The use of lithium organoborates not only improves the yield, but also increases the enantioselectivity. For example, ($E$)-'butyl hex-2-enoate 39 reacts with lithium phenylborate (generated in situ from phenyllithium and trimethylborate) in the presence of $[\text{Rh}(\text{acac})(\text{C}_2\text{H}_4)_2]/\text{BINAP}$ in dioxane with one equivalent of water (to lithium phenylborate) at 100°C to produce 40 in 92% yield and 96% enantiomeric excess.

![Scheme 16](image)

It is thought that the addition of one equivalent of water is necessary to generate the reactive Li[PhB(OMe)$_2$(OH)] species or PhB(OMe)(OLi) from Li[PhB(OMe)$_3$]. This is supported by the fact that PhB(OMe)$_2$ does not react with cyclohexenone in the absence of an additive, but upon addition of lithium hydroxide the reaction is driven to completion. Interestingly, cyclic enones afford higher yields when boronic acids are used instead of lithium organoborates.
1.2.4 Additions To Dehydroamino Acid Derivatives

α-Amino acids are important building blocks in drug discovery the production of a wide variety of substituted phenylalanine-type α-amino acids have recently been synthesised by Frost and Chapman. They revealed an efficient rhodium-catalysed conjugate addition of boronic acids to α,β-dehydroamino acid derivatives using only water as a solvent (Scheme 17).\(^{25}\) Initial studies with dehydroalanine derivative 41, in water gave disappointing results with a maximum 30% yield obtained with 1-naphthaleneboronic acid and [Rh(COD)Cl]₂, this low yield is proposed to be as a result of the intolerance of the acrylate to the aqueous conditions. The introduction of the phthalimide nitrogen protecting group and esterification of the free acid group, resulted in a stable substrate which could undergo 1,4-addition. Ethyl α-phthalimidoacrylate 43 reacted with 1-naphthaleneboronic acid to give a 98% yield of 44 after 24 hours. Both protecting groups can then be cleaved under acidic conditions (6N HCl/AcOH, 4/1) to furnish the unnatural α-amino acid hydrochloride salts in good yields (Scheme 17).
Unfortunately when the asymmetric 1,4-addition was performed on these substrates the phthalimide derivative 43 gave only a less than 5% ee (Scheme 18). However when 41 was reacted with 1-naphthaleneboronic acid in the presence of \([\text{Rh(acac)}(\text{C}_2\text{H}_4)_2]\) and Pringle’s, Binol derived diphosphite ligand, 45 N-acetyl-3-(1-naphthyl)alanine methyl ester 42 was produced in a 91% yield and 72% ee. It is interesting to note that the reactions could no longer be performed in water and that BINAP affords a racemic mixture of products.
Reetz also demonstrated the 1,4-addition of phenylboronic acid to α-acetamido acrylic acid ester 41. This produced phenylalanine derivative 46 in 100% conversion and 70% ee when [Rh(acac)(C₂H₄)]₂/phosphonite 47 is used in dioxane/water (10/1) at 100°C for 5 hours. This is increased to 76% ee when three equivalents of NaF were added (Scheme 19).
Chapter Two

Rhodium-Catalysed Acylations

Genet et al. facilitated the rhodium-catalysed 1,4 addition of dehydroamino esters 41 with potassium organotrifluoroborates to produce alanine derivatives of type 46 (Scheme 20). It was shown that potassium trifluoro(organo)borates were able to carbometallate dehydroamino esters with high efficiency in the presence of a rhodium catalyst. This reaction allowed the formation of various alanine derivatives in good to high yields (≥ 98%). In contrast to similar reactions a variety of amino acid protecting groups were tolerated under the reaction conditions. A brief study of alkenyl trifluoroborates proved that while they are less successful than their aryl counterparts they still produce the addition products in reasonable yields.

Scheme 19

Scheme 20
Chapter Two

Rhodium-Catalysed Acylations

1.2.5 Additions To α,β-unsaturated amides

The rhodium-catalysed 1,4-addition of organoboronic acids to α,β-unsaturated amides is successfully achieved under the Miyaura conditions of [Rh(acac)(C₂H₄)₂]/BINAP in dioxane/water at 100°C (Scheme 17). However, the reaction proceeds at a reduced rate, to the esters and enones, and requires one equivalent of base to obtain complete conversion. Potassium carbonate was found to be the best furnishing 85% yield and 93% ee of the addition product 49 after 16 hours. It is worthwhile to note that not only was the reaction inhibited by the addition of 5mol% HCl, but it could be restarted on addition of 15mol% K₂CO₃. This is attributed to the formation of the more active [Rh(OH)] catalyst (see mechanistic studies 1.3). A variety of α,β-unsaturated amides were successfully reacted under these conditions, especially for the addition of electron deficient arylboronic acids, but A-V-disubstituted crotonamides were found to be unreactive.

\[
\text{PhB(OH)₂} \xrightarrow{[\text{Rh(acac)(C₂H₄)₂}]/(R)\text{-BINAP}} \text{dioxane/H₂O (6/1) 100°C, 16h} \quad \text{PhO} \quad \text{no base} = 67\% \text{ yield} \quad 93\% \text{ ee} \\
0.05 \text{ equiv. K₂CO₃} = 85\% \text{ yield} \quad 93\% \text{ ee}
\]

Scheme 21

Lactam 52 is employed in the synthesis of (-)-paroxetine 50 and can be synthesised through the rhodium-catalysed 1,4 addition to its α,β-unsaturated counterpart 51 as demonstrated by Hayashi (Scheme 18). Using the standard conditions of [Rh(acac)(C₂H₄)₂]/(R)-BINAP, dioxane/water (10/1) at 100°C for 16 hours gave lactam 52 in 70% yield when phenylboronic acid was used, but a disappointing 17% when 4-fluorophenylboronic acid was used; although the product was obtained with a high ee (92-3% ee) in both cases. This dramatic reduction in yield was attributed to the 4-fluorophenyl rhodium(I) intermediate being more susceptible to protonolysis.
thus destroying the aryl group before the addition can be accomplished. To inhibit this, the reaction was performed at 40°C with 4-fluorophenylboroxine and the amount of water was reduced to one equivalent to boron. Under these conditions the yield increased to 63% and the enantioselectivity also improved to 97% (Scheme 22).

\[ \text{(-)-Paroxetine 50} \]

&\quad 97\% \text{ ee}
\end{align*} \]

\[ \text{Scheme 22} \]

Genet and co-workers continued their work with potassium trifluoroborates to the synthesis of chiral β-arylamides 49 from crotonamides 48 (Scheme 23).\(^3\)\(^0\) It was observed that whilst the addition of base had no effect on yield, the selectivity diminished considerably from 93% ee with no additional base to 64% ee with 10% potassium fluoride. This however was not the case with boronic acids where no variation was observed. Further studies where the two boron sources were run under identical conditions and followed by GC highlighted the following points:

The potassium(trifluoro)organoborates have an induction period of 10 minutes but the reaction had reached completion after 1 hour, whereas the boronic acid reacted
immediately but reached a 62% maximum after 1 hour 40 minutes. The induction period is postulated to be due to the formation of either another more active rhodium catalyst or a different boron species.

A variety of potassium(trifluoro)organoborates were reacted under optimised conditions to afford a range of chiral β-arylamides in high yields and selectivities. Electron-withdrawing and electron-donating groups on the aryl group had no effect on yield or selectivity (Scheme 23).

### 1.2.6 Alkenyl Phosphonates

Optically active phosphonic acid derivatives are important compounds because of their synthetic utility as chiral building blocks as well as their potential biological activity. Despite their potential the 1,4-addition to alkenylphosphonates has remained a relatively uncharted area, this may be attributed to their low reactivity to 1,4-addition. Hayashi and co-workers found that to achieve this the standard 1,4-addition conditions needed to be modified to include the use of phenylboroxine and one equivalent of water to boron. Alkenyl phosphonate (E)-53 reacted with phenylboroxine in the presence of [Rh(acac)(C$_2$H$_4$)$_2$/BINAP in dioxane at 100°C with the addition of one equivalent to boron of water, to yield alkyl phosphonate 54 in 94% yield and 96% ee (Scheme 24).

This reaction shows the crucial part that water has to play, as without water the reaction almost grinds to a halt with less than 5% yield. However, more than one equivalent to boron of water leads to increased hydrolysis of boronic acid/boroxine and catalyst deactivation.
The use of (S)-µ-BINAP 56 which has diphenylphosphino and bis(3,5-dimethyl-4-methoxyphenyl)phosphino groups at the 2 and 2' positions on the 1,1'-binaphthyl skeleton produced alkyl phosphonate (S)-54 in 88% yield and 96% ee which is comparable to the results achieved with standard (S)-BINAP (84% yield, 95% ee). It is interesting to note that using (Z)-alkenyl phosphonate instead of the (E)-isomer results in the product alkyl phosphonate with the opposite configuration (R)-54 in the presence of (S)-µ-BINAP. This change in configuration is also observed when (S)-BINAP is used with both (E)-53 and (Z)-53 being phenylated from the si face irrespective of the E,Z-geometry of the 1-propenyl moiety.

1.3 MECHANISTIC STUDIES

Hayashi recently reported a detailed insight into the important steps for the catalytic cycle of 1,4-additions to cyclohexenone. This section of the review will begin with an outline of this catalytic cycle followed by a more detailed look at the individual steps and intermediates, drawing on published experimental results.

1.3.1 Overview

Scheme 25
The catalytic cycle for the rhodium-catalysed 1,4-addition of aryl and alkenyl-boronic acids to α,β-unsaturated compounds is encapsulated above using cyclohexenone as an example.

This can be summarised using the following steps:

1. Formation of the active catalyst 57
2. Transmetallation of the aryl- or alkenyl species to the rhodium centre from the boronic acid to form the phenyl rhodium 58
3. Coordination/insertion of the enone to form the oxy-π-allylrhodium complex 59
4. Hydrolysis of 59 to afford the desired 1,4-addition product and regenerate the active catalyst.

### 1.3.2 Active Catalyst Generation

The precatalyst is customarily a bis(phosphine)rhodium(I) complex with either chloride or acac as a labile ligand. Transmetallation of the boron source with this complex is typically very slow, during which time, hydrolysis of the acac complex 60 into the [Rh(OH)(bis-phosphine)] 57 complex takes place. This complex is much more active towards transmetallation with boronic acids.

The acac ligand retards the transmetallation step due to the high stability of the [Rh(acac)] moiety and so [Rh(acac)] complexes require heating to 60°C or above for transmetallation to proceed. The use of rhodium hydroxide complexes [Rh(OH)] allow this reaction to proceed at lower temperatures with the transmetallation occurring at ambient temperature. This can be seen by the addition of phenylboronic acid to cyclohexenone catalysed by [Rh(OH)(BINAP)] at 35°C to give quantitative yields of 3-phenylcyclohexanone which is >99% enantiomerically pure. Reaction at this lower temperature is desirable as it suppresses the hydrolysis deboronation side reaction reducing the need for excess boronic acid, furthermore, the enantioselectivity is generally higher at this temperature.
If the $[\text{Rh(OH)}]$ species is formed \textit{in situ} from $[\text{Rh(acac)}]$ complex an equilibrium between these two species will be observed. $[\text{Rh(OH)}]$ reacts quickly with the excess acac ligand to reform $[\text{Rh(acac)}]$ which can then slowly transmettleate or slowly create the $[\text{Rh(OH)}]$ species. This equilibrium has a detrimental effect on the catalyst activity leaving most of the catalyst as the ineffective $[\text{Rh(acac)}]$ species. Therefore, more forceful conditions are often required for a more effective turnover, since even after being through the cycle once, rhodium may form the less active $[\text{Rh(acac)}]$ species again.

\textbf{Scheme 26}

Evidence for the \textit{in situ} generation of a $[\text{Rh(OH)}]$ complex can be found in stoichiometric and catalytic transformations. Hayashi has shown that the treatment of $[\text{Rh(BINAP)Cl}]_2$ with KOH in THF and water generates the hydroxo-bridged complex 57 (Scheme 27).\textsuperscript{32}

\textbf{Scheme 27}
Mirroring the conditions found in the majority of 1,4-addition reactions, the formation of this species in the presence of base, explains the inhibitory effects of a too acidic medium. In stoichiometric experiments the hydroxy bridged rhodium species \([\text{Rh}(\mu-\text{OH})(\text{BINAP})]_2\) undergoes complete transmetallation with phenylboronic acid at room temperature in 30 minutes. The enhanced reactivity of the rhodium hydroxo complex 57 is in part due to the high oxophilicity of boron.

### 1.3.3 Transmetallation

Ample evidence exists for the transmetallation of the arylboronic acid with the rhodium hydroxide species 57 in the form of many stoichiometric reactions of rhodium complexes with various organoboranes.

Aresta was the first to explore the transmetallation process between rhodium complexes and aryl organometallic reagents (Scheme 28).\(^{33}\) Complex 61 was formed when \([\text{Rh(dppe)Cl}]_2\) was treated with sodium tetraphenylborate in benzene. Treatment of complex 61 with \(>10\) atm. \(\text{CO}_2\) in DCM a new rhodium species was detected and characterised as \([\text{Rh(dppe)(\eta^5-\text{PhBPh}_3})(\text{CO}_2)]\) 62. Once the pressure was reduced this reverted back to the original complex 61. When complex 61 was heated in acetone under \(\text{CO}_2\) (>10 atm.) a species bearing a benzoate ligand was formed, 63. For this complex to arise, transmetallation of a phenyl group from the tetraphenylborate ligand must have occurred followed by insertion of \(\text{CO}_2\).
Chapter Two

Rhodium-Catalysed Acylations

Rhodium(I) $\eta^6$-PhBPh$_3$ complexes formed through coordination of the aryl group to the rhodium in a $\eta^6$-fashion have been prepared with many ligands including phosphates, bidentate and monodentate phosphines as well as a variety of olefin ligands.$^7$

### 1.3.4 Formation of reduced aryl side product (Ar-H)

After transmetallation it is possible that the aryl-rhodium complex 58 can form the reduced aryl (Ar-H) as a side product in one of two ways (Scheme 29). Hydrolysis of the aryl-rhodium bond leads to the active [Rh(OH)] complex 57 being reformed and gives protonated arene, Ar-H. This occurs through coordination of water to rhodium with subsequent protonation of the Rh-C bond. Alternatively oxidative addition of water to rhodium creates a hydridohydroxyarylrhodium(III) complex which can form the reduced aryl product, through reductive elimination.

Evidence for the production of the reduced aryl product can be seen in the treatment of Vaska-type phenyl complex 64 with acetic acid which generates benzene as does treatment of the same complex with HCl (Scheme 29).$^{34}$ This occurs through protolytic cleavage of the rhodium-carbon bond to generate benzene. This oxidative addition/reductive elimination process has been observed with rhodium hydride.
complexes with deuterated water or deuterium to generate deuterated aromatic hydrocarbons.\textsuperscript{35,36}

![Scheme 29](image)

In addition to water performing this reaction boronic acids themselves (or other hydroxyl containing organometallic compounds) may mediate this process. This side reaction is suppressed through either reduction of the amount of water present, lowering of the temperature or the use of other organoboranes such as boroxines and BF$_3$K salts.

### 1.3.5 Alkene Co-ordination/Insertion

Once the rhodium aryl species has been formed, facially selective coordination of the alkene occurs followed by insertion of the alkene into the Rh-C bond. This carborhodation produces the new carbon-carbon bond and the rhodium oxa-$\pi$-allyl species $59$. In addition to making the alkene more electrophilic, the presence of an electron withdrawing group on the olefin favours binding to the electron-rich rhodium(I) metal. This increased binding affinity of the alkene results in fewer equivalents of boronic acid being required since the coordination occurs before there is chance for hydrolysis of the aryl group. The rhodium-aryl complex then delivers the aryl nucleophile to the $\beta$-carbon of the alkene generating the oxa-$\pi$-allyl rhodium complex $59$. Protonolysis then liberates the 1,4-addition product and regenerates the active [Rh(OH)] complex $57$. 

- 37 -
This is proven through the stoichiometric reaction of complex 65 with cyclohexenone 3 to generate the 1,4-addition product 4 with the same sense of induction and enantioselectivity as the catalytic reactions (Scheme 30).^{32}

\end{align*}
\]

Scheme 30

### 1.4 ADDITION TO ALKENES: ADDITION VS. HECK

The rhodium-catalysed addition of organoboranes to alkenes is more complicated since it can proceed through two paths; either, addition-hydrolysis, which produces the 1,2-addition product, or addition-elimination which produces a Heck type product (Scheme 31).

\[
\begin{align*}
\text{R} & \quad \text{addition-elimination} \\
\text{addition-hydrolysis} & \quad \text{R}
\end{align*}
\]

Scheme 31

Lautens has demonstrated that certain heteroaromatic alkenes can be used in 1,2-addition reactions.^{37} For example, reaction of 2-vinylpyridine with 2.5 equivalents of phenylboronic acid and [Rh(COD)Cl]_2 with TPPDS (a water soluble phosphine ligand) in the presence of sodium dodecyl sulphate (SDS – a phase transfer reagent) in water at 80°C gives addition product in 84% yield (Scheme 33). The addition of SDS to the reaction solution results in a reduced amount of boronic acid being consumed from hydrolytic deboronation and increases the rate of the addition reaction. This was especially pronounced with the use of polar functional groups on the arylboronic acid. A variety of arylboronic acids were tested with similar results, the success of these additions being dependent on the location of the heteroatom.
within the aromatic ring. Successful reaction occurs if the nitrogen is in the ortho or para position, however no reaction was observed with 3-vinylpyridine i.e. when the nitrogen is in the meta position.

This can be explained by considering the mechanism of reaction. It could be argued that coordination of ortho-nitrogen atom of intermediate 66 will act as a driving force stabilising the resultant complex so that hydrolysis of the rhodium-carbon bond is favoured. The successful reaction of 4-vinylpyridine (which is unable to coordinate in this manner) implies that tautomersiation of intermediate 66 to the amide 67 could occur followed by protonation to liberate product and regenerate the catalyst (Scheme 32). This is supported by the low yield when 3-vinylpyridine is used which is not capable of this tautomersiation.

However, if styrenyl olefins are used, Heck-type addition followed by β-hydride elimination occurs (Scheme 33). Olefin 70 reacted with phenylboronic acid (2.5equiv.) in the presence of [Rh(COD)Cl]2/TPPDS, Na2CO3 and SDS to give 77% yield of Heck product 71. Most notably this reaction demonstrates that the addition reaction can occur in water despite previous reports that the presence of water accelerates deboronation, rendering the organoborane useless.
Chapter Two  
Rhodium-Catalysed Acylations

This was further demonstrated by Zou and co-workers who showed that when α,β-
unsaturated compounds were reacted under the optimised conditions of RhCl₃ (3 
moL%), PPh₃ (12 mol%) in toluene/water, with a 2/1 ratio of olefin/boronic acid at 
100°C to produce the Heck-type product. The olefin structure had a marked effect 
on the production of this product. Parent acrylate 72 (Scheme 34), reacted smoothly 
however substituted acrylates such as methyl methacrylate gave the α,β-unsaturated 
esters in only a 7% yield indicating that the steric bulk of the alkene was important. 
However, both electron donating and withdrawing groups on the boronic acid, 
proceeded to give the addition products in modest to high yields, indicating that 
enolisable substrates can undergo Heck-type reactions in aqueous conditions.

Tomioka has extended the 1,4-addition reaction to include the addition to N-
tosylarylimines 74 (Scheme 35). Chiral amidomonophosphane ligand 7 afforded a 
range of diarylmethylamines 75 in good yields and high selectivity when used in 
conjunction with [Rh(acac)(C₅H₄)₂] in propanol at 60-100°C for 3 hours. It was 
found that although phenylboronic acid gave moderate yields, the chemical yield 
could be further improved upon without loss in selectivity by using phenylboroxine

Scheme 33

Scheme 34

- 40 -
resulting in the product in 95% yield and 80% ee as opposed to the 72% yield for phenylboronic acid. Manipulation of the imine also improved selectivity as position of the substituents on the phenyl ring greatly affected selectivity with 4-Me giving 52% ee, 3-Me gave 56% ee and 2-Me gave 74% ee. As the trimethyl silyl (TMS) group can easily be converted to a proton or a halogen, 2-TMS benzaldehyde imine was prepared and reacted in high yields and selectivity (78% ee).

[Chemical Structure]

1.5 ADDITION TO ALKYNES

Rhodium-catalysed hydroarylation of internal alkynes was first described by Hayashi. Trisubstituted alkenes were produced in high yield and isomeric purity from both activated and unactivated alkynes through the use of \([\text{Rh(acac})(C_2H_4)_2]/\text{dppp}\) in dioxane/water (10/1) at 100°C (Scheme 36). (E)-4-Phenyl-4-octene 76 was generated from 4-octyne 77 in 87% yield and >20/1 selectivity. By increasing the amount of phenylboronic acid added from 1.2 equivalents to 5, this yield can be increased to 95% with no loss in selectivity. High regioselectivities are observed with alkynes substituted with electron withdrawing groups such as esters or phosphonates for example 78, 79 and 80. However, unsymmetrical substrates without electron-withdrawing functionalities produce a mixture of regioisomers 81.
Chapter Two
Rhodium-Catalysed Acylations

Interestingly, when these reactions are run in deuterated water it is the ortho position of the coupled phenyl ring that is labelled and not the vinylic position (Scheme 37). Analogously, when d⁵-phenylboronic acid is used, a 1,4-deuterium shift occurs to give the vinylic deuterated alkene.

Scheme 37
This can be rationalised by considering the mechanism (Scheme 38). Synchroncarborhodation of the alkyne with the arylrhodium(I) species generates the vinylrhodium complex 83 which undergoes ortho C-H insertion on the adjacent phenyl ring producing the rhodium(III) complex 84. Subsequent reductive elimination of the alkene and hydride ligand produces the vinylic C-H bond and a new aryl-rhodium species 84. Hydrolysis of this gives 85 and regenerates the catalyst. A closer examination of the potential side reactions in the catalytic cycle reveals a delicate balance that is required to give 85 as the sole product. While 83 could undergo 1,4-migration, hydrolysis or reaction with another alkyne, only migration occurs. Similarly, 84 undergoes selective protonation instead of reacting with a second alkyne.

Rhodium-catalysed additions to alkynylpyridines using SDS and Na$_2$CO$_3$ were investigated by Lautens. The reaction of 2-(1-hexynyl)pyridine with phenylboronic acid, performed in the presence of [Rh(COD)Cl]$_2$ and ligand 90, Na$_2$CO$_3$ and SDS in water at 80°C for 3 hours, generated the hydroarylation product in 51% yield as a single regio- and stereo-isomer. Interestingly, 3- and 4- alkynylpyridines fail to afford any product, thus the nitrogen functionality must be adjacent to the alkyne for successful reaction. This selectivity is exemplified by the reaction of 86 which
produces 87 exclusively in a 54% yield through reaction only at the alkyne adjacent to the nitrogen functionality (Scheme 39). However the alkyne need not be directly connected to the pyridine ring, for example the reaction of 88 gives 89 as the sole regio- and stereo-isomer in 90% yield.

By examining the mechanism the origin of this directing influence can be seen (Scheme 40). Transmetallation followed by coordination of the alkyne generates complex 91 where both the pyridine and alkyne groups are coordinated. This binding mode will result in the delivery of the aryl group to the distal alkyne carbon and formation of the alkenyl rhodium complex 92. Protonolysis then regenerates the catalyst and liberates the product.
Michelet and Genet synthesised ligand 95 (Scheme 41) which they proposed would facilitate the rhodium-catalysed addition of arylboronic acids to alkynes without the need for adding SDS or base. Using [Rh(μ-OH)(COD)]₂ in conjunction with ligand 95 the reaction of phenylboronic acid and oct-4-yne gave the aryl alkene in 95% yield. However this was a mixture of the desired alkene 93 and the side product diene 94 (80/20). Interestingly only a very low conversion was observed with [Rh(acac)(C₅H₄)₂] or [Rh(COD)Cl]₂ as the rhodium source. The use of a biphasic toluene/water (1/1) system increased the selectivity so that 99% yield of alkene 93 was observed with 100% selectivity. The diene is thought to be produced through a second oxidative addition of oct-4yne before subsequent hydrolysis. A range of alkynes and arylboronic acids were reacted under these optimised conditions to give high yields in all cases. Furthermore, the catalyst was recycled by extracting all products from toluene and reusing the aqueous layer.
1.6 1,2-ADDITIONS TO CARBONYLS

As with 1,4-additions, 1,2-addition reactions are important transformations in forming carbon-carbon bonds in organic synthesis (Scheme 42). The addition of carbon nucleophiles to carbonyl compounds can also be achieved through Barbier and Grignard reactions amongst others. However, these reactions suffer from the necessity of protecting sensitive functional groups.

\[

\[\text{Me}_3\text{P} = 24\% \text{ yield}\]

\[\text{Pr}_3\text{P} = 88\% \text{ yield}\]

\[\text{Bu}_3\text{P} = 99\% \text{ yield}\]

Scheme 42

[Rh(acac)(CO)\(_2\)] in combination with a phosphine ligand has been shown to be an excellent catalyst for the 1,4-addition of arylboronic acids to enones. Miyaura et al. also demonstrated its ability at catalysing the 1,2-addition of arylboronic acids to aldehydes.\(^{42}\) Analogous to the findings in 1,4-additions, the reaction benefited from a large P-Rh-P angle and monodentate phosphine ligands were ineffective. The exploration of [Rh(acac)(COE)]\(_2\) in combination with a variety of phosphine ligands lead to the hypothesis that the activity of the phosphine ligands is actually linked more to the basicity and steric properties of the ligand and not solely the bite angle as previously thought.\(^{43}\) When bisphosphanes are employed the reaction is accelerated by ligands with a large bite angle; however, with monophosphines, basic trialkylphosphines with large cone angles, such as tri-‘butylphosphine are better. Previously the reaction proved to be sensitive to electronic effects both in the aldehyde and the arylboronic acids; the ideal combination being electron-rich...
arylboronic acids and electron-deficient aromatic aldehydes. However, the heightened reactivity reduced the sensitivity of the reaction to functional groups on both the aldehyde, and the arylboronic acid.

Despite the huge success of asymmetric 1,4-additions, enantioselective 1,2-addition remains poor, with the method reported by Hayashi producing the highest ee at 41%. Surprisingly the use of BINAP and DIOP, which were highly successful in 1,4-additions, gave racemic products. The asymmetric addition to naphthaldehyde was finally achieved by the use of (S)-MeO-MOP as ligand (Scheme 43). Treatment of phenylboronic acid and 1-naphthaldehyde with \([\text{Rh(acac)}(\text{C}_2\text{H}_4)_2]\) and (S)-MeO-MOP 9 in aqueous DME at 60°C generated the desired secondary alcohol 97 in 78% yield and 41%ee, with \((R)-\)selectivity (Scheme 43).

\[

Scheme 43

The importance of the rhodium complex counterion on the reactivity of the rhodium species was extensively researched by Frost et al.\(^4\) 1-Naphthaldehyde was reacted with 4-methoxyphenylboronic acid in the presence of cationic complex 98 which incorporates a bisoxazolidinone ligand (Scheme 44). Results indicated the rate of reaction is increased with greater Lewis acidity at the rhodium centre. Weakly coordinating anions such as carboranes (CB\(_{11}\)H\(_{12}\)) achieved the best results with an 85% yield after only 2 hours.

1.7 1,2- VS. 1,4-ADDITION

Miyaura et al. noted that by adapting the conditions, boronic acids could perform either a 1,4- or a 1,2-addition to \( \alpha,\beta \)-unsaturated aldehydes (Scheme 45).\(^{43}\)

Reaction of cinnamaldehyde 99 with phenyl boronic acid in the presence of [Rh(acac)(COE)$_2$/Bu$_3$P in DME/water (3/2) at room temperature produces 101 in a 90% yield with no sign of 1,4 addition.

The 1,4-addition reaction, however, favours the cationic rhodium complex [Rh(COD)(MeCN)$_2$][BF$_4$] in the absence of ligand in methanol/water (6/1) at room temperature which gives exclusively 100 in 88% yield. However if the temperature is raised to just 50°C a mixture of products is formed.
Chapter Two
Rhodium-Catalysed Acylations

The analogous 1,2-addition to aldimines has been reported. Initial experiments of the addition of boronic acids failed to give the desired amine due to hydrolysis of the imine to the aldehyde with subsequent 1,2-addition to form the alcohol.\textsuperscript{45} Tetraphenyl borate was a viable substitute for boronic acids, with all four phenyl groups transferred from the borane to the aldimine, using the cationic rhodium salt \([\text{Rh}({\text{COD}})(\text{MeCN})_2][\text{BF}_4]\) and dppb as ligand in anhydrous conditions. Although good outcomes were obtained with N-sulfonyl and benzoyl aldimines, \(n\)-butyl, benzyl and phenyl aldimines produced less than 10% conversion. As the best results are achieved with electron deficient aldimines, it can be assumed that the reaction proceeds through nucleophilic attack of the aryl group on the C=N bond. Due to the higher stability of N-sulfonyl aldimines to hydrolysis and their greater reactivity, Miyaura found it was possible to react them with boronic acids in anhydrous conditions (Scheme 46).\textsuperscript{46} Treatment of \textbf{102} with \([\text{Rh}({\text{COD}})(\text{MeCN})_2][\text{BF}_4]\) and two equivalents of 4-tolylboronic acid generated \textbf{103} in 99% yield. Arylboronic esters can also be employed, but must be used in conjunction with triethylamine to obtain high yields. Interestingly, \(\alpha,\beta\)-unsaturated imines could also be reacted to produce the 1,2-addition product \textbf{105} in the presence of \([\text{Rh}(\text{acac})(\text{COE})_2]\) and \(\text{Pr}_3\text{P}\).
1.8 TANDEM REACTIONS

Further to Hayashi’s work with $B$-Ar-9BBN (Scheme 9) it was found that the intermediate boron enolate could be coupled with an aldehyde.$^{47}$ This has been termed a tandem 1,4-addition-aldol reaction. The reaction of $B$-Ar-9-BBN, vinyl ketone 106 and aldehyde 107 catalysed by 3mol% of [Rh(OMe)(COD)]$_2$ proceeded in toluene at 20°C to give a high yield of the aldol-type product with high syn selectivity (Scheme 47). Changing the catalyst to [Rh(OH)((S)-BINAP)]$_2$ gave optically active products syn-(4S, 5R)-108 in 41% ee and anti-(4R, 5R)-109 in 94% ee.
Although the syn selectivity is low, the formation of the enantiomerically enriched products demonstrates that the reaction proceeds through an (oxa-π-allyl) rhodium complex 110 which is formed by the carborhodation of the vinyl-ketone 106 (Scheme 48). This undergoes aldol-type reaction with aldehyde 107 forming rhodium aldolate 111. If the boron-enolate intermediate was formed first, it would require transmetallation after the carborhodation of the vinyl-ketone but before the aldol reaction leading to a racemic product. Hence, the enantiomerically enriched products point to the formation of intermediate 111.
This protocol has since been extended by Krische to an intramolecular tandem-1,4-addition-aldol reaction. This was achieved through the use of ketone-enones such as producing the cyclic product in high yields (Scheme 49). These conditions were similar to the original Hayashi conditions of [Rh(acac)(C₂H₄)₂]/BINAP in dioxane/water at 100°C than the tandem 1,4-addition aldol conditions of above. In the use of [Rh(acac)(C₂H₄)₂]/(R)-BINAP, water is required to form the more reactive catalyst. This normally brings with it the problems of protonolysis. However this reaction can take place in the presence of an excess of water (five equivalents) as the intramolecular reaction of the intermediate with the ketone moiety is faster than the protonolysis by water.
Chapter Two

Rhodium-Catalysed Acylations

Zou found that reacting cinnamaldehyde 99 with boronic acid in biphasic conditions of RhCl₃ in combination with 4 equivalents PPh₃ and potassium carbonate in toluene/water at reflux yielded neither the 1,4-addition nor the 1,2-addition product, however a conjugate addition/cross coupling tandem reaction was found to occur (Scheme 50). Reaction of cinnamaldehyde 99 with phenylboronic acid gave 54% yield of β-phenylpropiophenone 114.

The mechanism is thought to proceed via transmetallation followed by oxidative addition of the C-H of the aldehyde group into the Rh-C(aryl) bond (Scheme 51). Intramolecular insertion of the C=C to Rh-H affords the ketene complex 115. Reductive elimination then ensues to release the strained intermediate 116, which then undergoes oxidative addition of water to release the product and afford the reactive catalyst.
Evidence for this can be observed using deuterated water as the co-solvent, leading to deuteration of the product at the α-position, indicating the hydrolysis of the Rh-C bond being involved. Using the deuterated aldehyde of cinnamaldehyde lead to β-deuterated product, indicating the C=C is self-reduced by the proton from the aldehyde. A number of arylboronic acids and cinnamaldehydes were able to react with moderate yields achieved in all cases.

1.9 RING OPENING REACTIONS

Miura’s research has explored transition metal catalysed domino or ‘merry-go-round’ sequential allylations. The addition of arylboronic acids to the strained alkene, 2-norbornene 117, was shown during this research to result in a tetra-alkylated arene 120 as the major product (Scheme 52). This is achieved through addition of phenylboronic acid in the presence of seven equivalents of norbornene 117, two equivalents cesium fluoride, and [Rh(COD)Cl]₂/dppp at 100°C in toluene. Reducing
the number of equivalents of norbornene increases the amount of 1,2-di and 1,2,3-tri-
(2-norbornyl)benzenes 118 and 119 products could be increased.

\[
\text{[Rh(COD)CI]}_2/dppp + \text{PhB(OH)}_2 \rightarrow \text{R} + \text{CsF, toluene, 100°C} \rightarrow \text{R} = \text{norbomyl} 118 119 120 \\
\begin{align*}
6\% & \quad 14\% & \quad 80\%
\end{align*}
\]

Scheme 52

This ‘merry-go-round’ multi addition reaction is thought to be due to the lack of water, the presence of which would hydrolyse the intermediate complex to the product before a further allylation can occur. Initial transmetallation generates the rhodium phenyl complex that coordinates to the exo face of norbornene (Scheme 53). Insertion of the alkene then leads to intermediate 121, which in the absence of a \(\beta\)-hydrogen to eliminate generates 122 through ortho C-H insertion followed by reductive elimination. This whole process can then occur up to three more times. After the third cyclorhodation step there is too much steric bulk around the arene to facilitate a further insertion of norbene, thus the unfavoured protonolysis step will occur to generate 120 and regenerate the active catalyst.
Scheme 53

Aryl and alkenylboronic acids can also be added to oxabenzonorbornadienes through ring opening across the bridging oxygen. Murakami achieved the best results using a combination of [Rh(COD)Cl$_2$] and two equivalents of P(OEt)$_3$ and two equivalents of NaHCO$_3$ in methanol at reflux yielded alcohol 123 in 80% yield (Scheme 54).$^{50}$ A variety of oxabenzonorbornadienes reacted smoothly, with the most noteworthy being the toleration of bromine on the aromatic ring (124) and the formation of 125 that demonstrates unsymmetrical substrates are able to react with high diastereoselectivity. The yield did however drop when two bridgehead methyl groups were present, such as 126 but the yield is still respectable at 53%.
In 2002, Lautens et al. reported modified conditions that afforded these types of alcohols with good yields (71-95%) and enantioselectivities (92-95%) (Scheme 55). Treatment of 127 with phenylboronic acid, aqueous cesium carbonate and [Rh(COD)Cl]_2/PPF-P'Bu_2 in THF at room temperature produces 128 in 91% yield and 95% ee as a single isomer. A range of boronic acids proved compatible, including vinyl species as well as aryl groups containing iodide functionalities, with high enantioselectivity achieved for all.
Scheme 55

Although these optimised conditions were unsuccessful for the addition of phenylboronic acid to oxabenzonorbornadiene 129, exchange of the boronic acid for phenylboronic ethylene glycol afforded 123 in 78% yield and 92% ee (Scheme 55).

Murakami and Lautens independently proposed similar mechanism for these ring-opening reactions, an outline of which is depicted in Scheme 56. Initial formation of the active [Rh(OH)] complex is followed by transmetallation of the organoboronic acid to the rhodium followed by the coordination of the oxabicycle through the sterically more accessible exo-face. Insertion of the alkene into the Rh-C bond generates complex 130 from where β-oxy-elimination proceeds to regenerate the olefin and to form an alkoxyrhodium species, 131, which undergoes protonolysis producing the alcohol and regenerating the active catalyst.
Murakami postulated that an arylrhodium(I) species is more electron rich than a rhodium(I) halide or a cationic rhodium(I) species and so more easily oxidised to a rhodium(III) species during insertion between the carbonyl and α-carbons. From this it was proposed that addition of phenylboronic acids to cyclobutanones would result in an addition/ring opening mechanism resulting in the formation of a butyrophenone derivative (Scheme 57). Reaction of 3-phenylcyclobutanone 132 with o-tolylboronic acid in the presence of [Rh(acac)(C₅H₄)₂]P(‘Bu)₃ and cesium carbonate resulted in the formation of 90% butyrophenone derivative (resulting from the cleavage of the C(acyl)-C(α) bond and bonding of the o-tolyl group to the acyl carbon) and 10% tertiary cyclobutanol 135 (resulting from addition of the o-tolyl group to the carbonyl group) after 3 hours (Scheme 57). After 24 hours no tertiary cyclobutanol was detected suggesting that 135 isomerises into 134. However this isomerisation/ring opening process does not happen when 135 is heated in the absence of catalyst. This led them to believe the mechanism to be via the addition of arylrhodium to the carbonyl group of 132 followed by the ring opening of the
resulting rhodium alcoholate through β-carbon elimination, rather than via direct insertion of rhodium(I) between the carbonyl carbon and the α-carbon.

Scheme 57

1.10 MISCELLANEOUS REACTIONS

Miura has reported the reaction of tetraarylborates with anhydrides to produce simple ketones (Scheme 58).\textsuperscript{53} \([\text{Rh(COD)}\text{Cl}]_2/dppf\) catalysed the reaction of acetic anhydride with tetraphenylborate in toluene at 100°C to furnish 91% acetophenone after two hours. This was then extended to include a three-component coupling reaction of acetic anhydride, tetraphenylborate and norbornene. Using identical conditions, acetophenone was produced along with 60% of 136 through the three-component pathway. This product is created through transmetallation followed by insertion of the norbornene alkene into the Rh-C(aryl) bond. Oxidative addition of the anhydride followed by reductive elimination generates product 136 and regenerates the active catalyst.

\[
\begin{align*}
\text{136}
\end{align*}
\]

Scheme 58
Lautens has demonstrated the synthesis of indanes through reaction of norbornene and conjugated alkenyl boronic esters. The reaction of norbornene with boronic ester 137 catalysed by \([\text{Rh(COD)Cl}]_2\) in the presence of SDS and water resulted in the product in poor conversion. However, on addition of the water soluble ligand TPPDS and using toluene/water (1/1) as solvent, a 100% conversion was achieved, but unfortunately this constituted of a mixture of the two possible products. Switching to the more electron-rich and bulky water soluble ligand \(139\) (\(\text{'Bu-amphos}\)) resulted in a 95% conversion of solely the indane product 138 which was itself in a >20:1 diastereomeric ratio (the stereochemical configuration was assigned by 2D NMR and NOE experiments) (Scheme 59). This shows that the amphos ligand is responsible for the high activity and selectivity seen.

The mechanism is thought to follow transmetallation of the borane followed by carborhodation of the norbornene subsequent carbocyclisation via a 5-exo-trig process generated the rhodium enolate 140 before protodemetallation afforded the product and regenerated the active catalyst (Scheme 60).
In an extended paper, Lautens further explored this carbocyclisation through examination of norbornyl derivatives such as norbornadiene 141 which reacted well to give >90% yield of product 142 (Scheme 61).\(^\text{55}\) Surprisingly oxabenzonorbornadiene 129 inhibited the reaction leading to no product, this is thought to be due to oxidative addition into the strained C-O bond. This lack of reactivity is mirrored by the azabicyclic system 144, which also does not react. Although 145 proved to react well (90% yield) when substituents were introduced onto the bridgehead carbons, there were varied results. Disubstituted 146 did not react at all, but norbornene 147 with only one substituent present, afforded the product as a single diastereomer and regioisomer 147 in 87% yield. This is thought to be due to the shielding of the alkene by the bridgehead substituents, this sensitivity is increased when 150 is used, which has a large phenyl group substituents resulting in no reaction. However, reducing the size of the substituents, results in 60% yield of the single regio- and diastereo-isomer if 149 is used.
Carbocyclisation has been further explored by Lautens (Scheme 62), here, rather than a strained alkene, alkynes were explored as coupling partners.\(^{56}\) It had been previously reported that when using alkenes such as styrene no reaction was achieved. Unfortunately, utilising the previous conditions only 25% yield of product 151 was obtained. However, by changing the conditions to [Rh(COD)Cl\(_2\)] in combination with tri-’butylphosphonium tetrafluoroborate and performing the reaction in dioxane/water (10/1) yielded 99% of product 151 after three hours. An electron-withdrawing group on the alkyne proved essential, with alkynes containing either a phenyl or ester group reacting well. However, if both groups were present i.e. one on each side the yield was reduced due to the alkyne being too electron deficient. Pyridine groups were explored as possible electron-withdrawing groups.
and reacted well with the nitrogen in the 3- or 4-position, but no reaction was observed when in the 2-position.

![Reaction Scheme](image)

**Scheme 62**

Kabalka *et. al.* recently reported the direct aryl-allylation through the reaction of cinnamyl alcohol 152 with boronic acids catalysed by rhodium complexes (Scheme 63).\(^{57}\) Cinnamyl alcohol was coupled with 4-methoxyphenylboronic acid in the presence of [RhCl₃].3H₂O and Cu(OAc)₂ in the ionic liquid 1-butyl-3-methylimidazolium hexafluorophosphate (B₃m[P₆]), thus generating the allylphenyl 153 in 76% yield. Electron-rich boronic acids were found to generate products in higher yields than those that were electron-deficient, with ortho- and meta-substituted arylboronic acids typically affording lower yields than para-substituted ones. Due to the use of the ionic liquid the catalyst can be recycled with no significant loss of activity. The authors propose that oxidative addition of rhodium to the C-O bond of cinnamyl alcohol forms a π-allylrhodium complex, which in turn undergoes transmetallation with the boronic acid. Reductive elimination then follows forming the desired product and regenerating the catalyst.
1.11 CONCLUSION

This review has highlighted the significant advances in rhodium-catalysed additions of organoboranes in the past eight years. This progress has led to many new carbon-carbon bond forming reactions which are high yielding and often form one or two new chiral centres with significant selectivity. This combination of rhodium and organoboranes has performed an array of reactions including 1,4-addition, 1,2-addition, ring opening, and tandem 1,4-addition/aldol - frequently in demanding conditions and always demonstrating high level of tolerance to functional groups and reaction conditions. All of this places rhodium as a good contender to palladium, which dominates this area at the moment.

This direction of research is set to continue to grow with the new synthetic pathways to both old and new drug molecules requiring more tolerant and highly selective methods.

Rhodium-Catalysed Acylations
Chapter Two

2 RHODIUM-CATALYSED ACYLATIONS

2.1 AIMS AND OBJECTIVES

The object of this project is to exploit the rhodium/boron transmetallation process in an effort to develop a new synthetic route to ketones. This protocol is intended to compete with Friedel Crafts acylations without sustaining the same limitations incurred with some functional groups.

2.2 BACKGROUND

Ketones are of fundamental importance to synthetic chemistry; consequently there are a wide variety of methods available for their synthesis. Below is a brief overview of the most common methods when starting from acid chlorides 154-7, alcohols 158-9, alkenes 160-1, alkyl halides 162, alkynes 163, simple aromatics 164, nitriles 165, amides 166 and anhydrides 167. This highlights that the existing protocols for the preparation of the starting preparations are limited in both selectivity and general applicability.

These procedures encompass the use of Grignard and coupling reagents, as well as reactions such as Friedel Crafts acylations, oxidations and carbonylations. Despite this array there are no truly general methods, with disadvantages and limitations being seen for each method. For Grignard and oxidation systems often the product is just as reactive as the starting material meaning that careful monitoring of conditions must be used to ensure the reaction stops at the required product. Organocadmium regents are very toxic and so should be avoided whilst organolithium-cuprates are unstable and cannot be stored for extended periods.

Due to the nature of Friedel Crafts acylations, the presence of certain functional groups can dramatically affect the efficiency of the reaction. If an electron-withdrawing group is present, the electron-deficient aromatic ring will be less reactive and in the case of nitrobenzene will not react at all. On the other hand electron-donating groups enhance the reactivity and the reactions proceed faster with a greater overall yield. The regioselectivity of the reaction is also largely dependent
on the resonance forms of the reactive intermediate. As can be seen in Scheme 65 electron-withdrawing groups will direct the acyl group to the meta position and electron-donating groups direct the acyl group to ortho and para positions - often leading to a mixture of products. In general para attack predominates for alkyl benzenes but the percentage ortho attack increases with the electrophilicity of the acylium ion; as much as 50% ortho product is observed with formylium and 2,4-nitrobenzoylium. Both of these effects in combination cause serious limitations to this method.

![Scheme 65](image.png)

**2.3 PROPOSED REACTION**

The anticipated reaction involves the addition of an arylboronic acid to an activated acyl group, such as an anhydride, in the presence of a rhodium catalyst to form an aromatic ketone.

![Scheme 66](image.png)
It was reasoned that the anhydride will coordinate to rhodium via the π-electrons of the carbonyl allowing the coupling of the aryl group to the anhydride in a 1,2-addition fashion, expelling the desired arylketone and forming a rhodium carboxylate with the corresponding acid. This protocol is based on Hayashi’s proposed mechanism for the rhodium catalysed 1,4-addition of arylboronic acid to enones (see Literature Review 1.3).[^32] The three main stages of this mechanism will comprise of:

1. **transmetallation of an aryl group from boron to rhodium**[^58].

2. **insertion of carbonyl into the aryl-rhodium bond expelling the desired product and forming the rhodium enolate**[^59].

3. **hydrolysis giving the corresponding acid and hydroxorhodium species**[^57].

![Scheme 67](image-url)

[^32]: The text refers to Hayashi's proposed mechanism for the rhodium catalysed 1,4-addition of arylboronic acid to enones.
[^58]: Transmetallation of an aryl group from boron to rhodium.
[^59]: Insertion of carbonyl into the aryl-rhodium bond.
[^57]: Hydrolysis giving the corresponding acid and hydroxorhodium species.
Many organoboron compounds are air sensitive, and in some cases pyrophoric, while those containing boron-hydrogen, boron-nitrogen, boron-halogen, and to a lesser extent, boron-oxygen bonds, are easily hydrolysed. Boronic acids in contrast are usually crystalline solids that are stable to both air and moisture. They are also of relatively low toxicity (phenylboronic acid $LD_{50}$ oral-rat = 740mg/kg] and environmental impact. Furthermore, they offer advantages over organolithium, organomagnesium or other organometallic reagents due to their tolerance to a wide variety of functional groups.$^{37}$

2.4 RHODIUM CATALYSED ADDITION OF BORONIC ACIDS TO ANHYDRIDES

2.4.1 Preliminary Studies

\[
\begin{align*}
\text{O} & \quad \text{O} \\
168 & \quad 169 \\
\text{[Rh(acac)(COD)]} & \\
\text{DME, 80°C, 16hrs} & \quad 170 \\
& \quad 16\% \text{ yield}
\end{align*}
\]

Scheme 68

To assess the reactivity of phenylboronic acid 169 to acetic anhydride 168, 5mol% of [Rh(acac)(COD)] was added to a solution of phenylboronic acid (1.6equiv.) and acetic anhydride (1equiv.) in DME and stirred for 16 hours at 80°C (Scheme 68). These conditions were first published by Miyaura for the 1,4-addition of arylboronic acids to enones however in our reaction these conditions produced only a 16% yield of acetophenone 170.$^{8,74-77}$ Whilst this was disappointingly low, the observed formation of acetophenone was encouraging as it was indicative of an effective protocol for ketone synthesis.
2.4.2 Catalyst Development

A wide variety of rhodium catalysts are used in 1,4-addition reactions however there is a trend towards [Rh(acac)] based catalysts being more reactive in additions to activated olefins.\(^3\) This is due to the [Rh(acac)(BINAP)] catalyst forming the more active [Rh(OH)(BINAP)]\(^2\).\(^3\) This catalyst is much more efficient at transmetallation which can even be achieved at room temperature. [Rh(BINAP)Cl]\(^2\) however does not form this catalyst and requires the addition of potassium hydroxide to do so. As the addition to anhydrides also involves the transmetallation of the aryl group from boron to rhodium, it was postulated that [Rh(acac)] based catalysts should perform well. Therefore, the activity of these and a variety of other catalysts were examined for this procedure.

\[
\begin{align*}
\text{O} & \quad \text{O} & \quad \text{OH} \\
\text{168} & \quad \text{169} & \quad \text{rhodium cat.} \\
\text{DME, 65°C, 16hrs} & \quad \text{170}
\end{align*}
\]

Scheme 69

It is important to first note that in the absence of catalyst no reaction takes place.

Three different [Rh(acac)] core catalysts were investigated in the absence of phosphine ligands (Table 1). Unfortunately the highest yield observed was a disappointingly low 27% with [Rh(acac)(nbd)], and interestingly [Rh(acac)(C\(_2\)H\(_4\))\(^2\)] proved completely unreactive. However, when the acac ligand is replaced with chloride (e.g. [Rh(COD)Cl]\(^2\)) there was a marked increase in yield in all cases except [Rh(nbd)Cl]\(^2\). This result is the opposite from previously noted trends and is most strongly seen in the case of [Rh(C\(_2\)H\(_4\))\(^2\)Cl]\(^2\) which gave an 87% yield. To complete the range of rhodium catalysts tested RhCl\(_3\).H\(_2\)O, [Rh(OAc)\(_2\)].H\(_2\)O and [Rh(CF\(_3\)CO\(_2\))\(^2\)]\(^2\) were all examined but only [Rh(CF\(_3\)CO\(_2\))\(^2\)]\(^2\) was reactive, but only gave a small yield of 34%.

To assess whether the presence of a phosphine ligand would improve the activity of the catalyst, [Rh(BINAP)Cl]\(^2\) was created \textit{in situ} from [Rh(C\(_2\)H\(_4\))\(^2\)Cl]\(^2\) and two
equivalents of rac-BINAP. Surprisingly the yield dropped, although only slightly to 83%, leading us to believe that [Rh(BINAP)Cl]₂ is of similar reactivity to [Rh(C₂H₄)₂Cl]₂ in this case.

\(^c\) generated in situ from [Rh(C₂H₄)₂Cl]₂ and BINAP.

**Table 1**
N-Heterocyclic carbenes (NHCs) constitute a class of ligands that exhibit pronounced σ-donor properties but are very poor π-donors. They are easily generated from the corresponding imidazolium salts and have been employed with considerable success in various catalytic transformations involving the turnover of an electron rich transition metal intermediate. In particular, their use has tended towards olefin metathesis and palladium catalysed cross coupling reactions.

Furstner utilised these ligands when he demonstrated the rhodium-catalysed addition of organoboron compounds to aldehydes carried out in the presence of the sterically hindered imidazolium salt 173 (Scheme 70).

This research showed that the reaction could proceed with the NHC being formed in situ from the imidazolium salt with a strong base. Phenylboronic acid was added to para-methoxybenzaldehyde 171 in the presence of RhCl₃·3H₂O, NHC 173 and sodium methoxide to produce 172 (Scheme 70). The scope of the reaction proved wide-ranging, and chemoselectivity of aldehydes over keto groups was demonstrated. Electron-rich and electron-poor aromatic aldehydes react with similar ease and even sterically hindered aliphatic aldehydes reacted well. However, limitations were observed when applying arylboronic acid derivatives bearing strongly electron-withdrawing groups. Thus, the attempted addition of para-nitro or
Chapter Two  

Rhodium-Catalysed Acylations

para-cyanophenylboronic acid to benzaldehyde by means of the present catalyst system proved unsuccessful. This failure is ascribed to the reduced nucleophilicity of these compounds, which makes the transmetallation to the rhodium catalyst unfavourable.

Given that RhCl₃·3H₂O is one of the cheaper rhodium salts it was decided to explore its application to our methodology for ketone synthesis (Scheme 71). Initial results were promising with a 56% yield after only 30 minutes (Table 2). However, this rate of reaction was not maintained as only an increase of 8% yield was achieved in the next 1.5 hours. These conditions were then unable to compete with [Rh(C₂H₄Cl)]₂ which generated a yield of 86% in 16 hours and so this route was not pursued any further.

Table 2

2.4.3 Different Acyl Sources

The results of the reaction of boronic acids and acetic anhydride confirmed the feasibility of rhodium-catalysed acylation reactions. To improve the versatility of the process, a range of different acyl sources were explored.

One such possible acyl source is a thiol ester. This has already been applied to the synthesis of simple ketones by Liebeskind. Coupling of thiol ester 175 with boronic acid 176 in the presence of \text{Pd}_{2}\text{dba}_3/\text{TFP} and copper (I) thiophene-2-carboxylate (CuTC) in strictly nonbasic conditions produced ketone 177 in 88% yield (Scheme 72).

\]

\[
\text{THF, 50°C, 18h}
\]

88% yield

Scheme 72
Although yields obtained were generally high, this reaction is not ideal as thiol esters are toxic. It was also professed that mixed anhydrides were not intermediates in this reaction with the thiol esters not reacting with CuTC either alone or in the presence of the palladium catalyst. Due to this report thiol esters will not be included in this investigation. However, acid chlorides, isoprenyl acetates and cyclic anhydrides were included in the substrates to be examined.

\(^b\) isolated yield after flash chromatography.

**Table 3**

Unfortunately when studied, both the acid chloride and the cyclic anhydride did not provide any product; isoprenyl acetate also gave a disappointingly low 32% yield (Table 3). This maybe due in part to the fact that they are less able to coordinate to the rhodium leading to an inability to form the activated acyl group especially in the
case of the cyclic anhydride. By re-examining the proposed mechanism (section 2.2) it can be seen that a second carbonyl group needs to be available to coordinate to the rhodium to form the rhodium enolate. This cannot be formed for acyl chloride and is unavailable due to steric hindrance with the cyclic anhydride. However the isoprenyl acetate shows some activity as the alkene group can coordinate. Also the presence of the chloride group will affect the electronics and dipole of the carbonyl double bond rendering it even less likely to coordinate.

![Scheme 73](image)

Due to the large number of carboxylic acids available the direct coupling of these with boronic acids would be very attractive. Unfortunately the reaction of carboxylic acid 178 failed to yield any product (Scheme 73). This led to the consideration of N-hydroxysuccinimide (NHS) esters of the carboxylic acids such as 179 which can be easily formed through the use of coupling reagents such as DCC. This proved successful with 179 furnishing a 64% yield of benzophenone (180). This offers a feasible alternative to the anhydride, should anhydride formation prove elusive or too costly.
2.4.4 Optimisation

To investigate whether the yield could be increased further a number of parameters were explored.

Solvent Study

Changing the solvent the reaction is performed in can alter the solubility of the reagents, as well as any catalyst intermediates. Thus an investigation of a range of solvents reacted at a variety of temperatures, in an attempt to avoid harsh reflux conditions, was performed (Table 4).

Two clear contenders were immediately apparent, DME and dioxane both proving very effective with yields of 85% and 83% respectively. Reaction of phenylboronic acid with acetic anhydride in a solution of DME/water (6/1) generated an 84% yield of acetophenone illustrating that the reaction is unaffected by water. Despite the comparable yield, DME/water was rejected as the solvent system of choice as the presence of too much water increases the hydrolysis of boronic acids, which could lead to a reduction in yield when more sensitive boronic acids are utilised. However this result was very useful as it indicated that the preferred solvent would not have to be rigorously dried. Dioxane was selected as the preferred solvent as its boiling point is higher thus enabling the reaction temperature to be raised for less reactive substrates without the need to resort to reflux conditions.

Time & Temperature Study

By elevating both the temperature and elongating the reaction times it can be seen that generally the yields increase. Thus, a study was performed investigating the effects of changing the reaction times at various temperatures (Table 5).

Table 5
When the temperature is raised from room temperature to 100 °C there is an increase in yield after 2 hours from 26% to 64% yield. Also at 65 °C the reaction gave only a 38% yield after 2 hours but increased to 89% after 24 hours. However on closer inspection it can be seen that there is a small reduction of yield in both cases. This is due to the increased prominence of side reactions and their products. These not only manifested themselves in slightly lower yields, but complicated the work up and purification stages. This effect was most pronounced when the reaction was
Chapter Two

Rhodium-Catalysed Acylations

performed at 100°C where a reduction of yield between 6 hours and 24 hours is observed (Graph 1).

![Temperature & Time Study](image)

**Catalyst Loading Study**

The study of the optimal catalyst loading proved once again that there is a fine balance in this reaction between the acceleration of the desired reaction and the production of unwanted side products. Although none of these side products were isolated they are likely to include benzene through hydrolysis of the boronic acid.

It is pleasing to note that a 33% yield can be achieved with catalyst loadings of as low as 0.1mol%. However, there is a decrease of 15% yield when the loading is increased from 3mol% to 5mol%. Thus, 3mol% is the optimum catalyst loading for a 16 hour reaction at 65 °C (Table 6).

Table 6

2.5 SCOPE OF REACTION

2.5.1 Range of Boronic Acids

Under these optimised conditions a wide range of boronic acids were examined (Table 7). It was useful to observe that although electronic effects may reduce the rate of the reaction, the composition of the product was unaffected by the nature and position of the substituent on the boronic acid. This versatility is in contrast to trends seen in Friedel Crafts acylation reactions, where the presence of deactivating groups such as a nitro group demonstrated a dramatic reduction in yield. Under the rhodium-catalysed system we observed only a modest reduction to 56% (entry 2) compared to 87% (entry 1). It should also be noted that the positioning of such groups does not influence the yield; the methoxy group (normally ortho, para
directing in Friedel Crafts) presents reasonable yields in both the para and meta positions with 67% (entry 4) and 69% (entry 5) yields respectively. Of particular note is the use of trans-2-vinylphenylboronic acid (entry 8) which not only reveals the ability of alkenylboronic acids to participate in the reaction but demonstrates the selectivity of these conditions in providing only acylation products rather than going further to the 1,4-addition products.

Table 8

Mixed Anhydrides

During our investigation Gooßen and co-workers developed a system whereby carboxylic acids are transformed into ketones. Since most carboxylic acids can easily be converted into anhydrides this would be done in situ allowing the coupling reaction to take place.

They first demonstrated the feasibility of the coupling of anhydrides and boronic acids in the presence of a palladium catalyst. Hexanoic anhydride 192 (1mmol) reacted with 4-methoxyphenylboronic acid (1.2mmol) in the presence of palladium (II) acetate (0.03mmol) and tri-\(p\)-methoxyphenylphosphine (0.07mmol). This produced a 91% yield of aromatic ketone 193 (Scheme 74). These conditions were generally successful for a variety of both anhydrides and boronic acids. However, for the best results different phosphine ligands are required depending on the steric
and electronic properties of the anhydrides. For example, for more electron-poor aryl derivatives triphenylphosphine or diphenylferrocenylphosphan are more effective.

Although the majority of anhydrides reacted well, pivalic anhydride proved too hindered to react at all. This opened up the opportunity for achieving an in situ activation of sterically less hindered carboxylic acids by generation of the corresponding mixed anhydrides. Para-methoxybenzoic acid 194 reacted with phenylboronic acid in the presence of pivalic anhydride 195 and palladium(II) acetate/ligand to produce only para-methoxybenzophenone 189 in 55% yield (Scheme 75). The amount of water present in the reaction proved crucial. In the absence of water less than 1% of the ketone was formed, with two equivalents the reaction almost reaches completion. However, with ten equivalents this drops to around 80% yield.
It was pleasing to note that when pivalic anhydride was applied under our conditions it did react with phenylboronic acid to furnish a 28% yield of ketone 197 (Table 9). Although this is a low yield it does show that even the most sterically challenging substrates are capable of reacting under these conditions. Unfortunately this negates the ability to form mixed anhydrides from pivalic anhydride and carboxylic acids in the same way that Gooßen accomplished ketone synthesis from carboxylic acids.\(^8\)

Fortunately synthesis of ketones from carboxylic acids can be achieved through the initial formation of the \(N\)-hydroxysuccinimide ester and its subsequent reaction. Both benzophenone and propiophenone were synthesised from phenylboronic acid and the appropriate NHS ester in 64% and 43% (Table 9, entries 3 & 2) respectively. By comparing the yield of the reaction of benzoic anhydride with phenyl boronic acid (76% yield) with that of the reaction of the phenyl NHS ester and phenyl boronic acid (64% yield) it can be seen that the NHS ester is slightly less reactive, but a good yield is still achieved.
### Chapter Two

**Rhodium-Catalysed Acylations**

#### 2.6 CONCLUSION

A new and widely applicable methodology for the synthesis of simple ketones has been established. The reaction requires low catalyst loadings and is unaffected by both air and the presence of a reasonable amount of water. It has been shown to be tolerant to a wide variety of functional groups and the yield is almost unaffected by both the position on the aromatic ring and steric bulk of such groups. This method could therefore be applied to complex organic synthesis through either the construction of the anhydride or the formation of the NHS ester.

CHAPTER THREE:
*Rhodium-Catalysed Additions To Itaconate Esters*
3 RHODIUM-CATALYSED ADDITIONS TO ITACONATE ESTERS

3.1 AIMS AND OBJECTIVES

The object of this project was to explore the 1,4-addition of organoboronic acids to dialkyl itaconate esters, the products of which are synthetically useful as they are important intermediates for the synthesis of many natural products; for example, matrix metalloproteinase inhibitor 199.82

![Figure 1](image.png)

Initial studies will focus on the racemic synthesis of 2-substituted succinic esters, through the study of a range of rhodium complexes and conditions. It was felt that aqueous conditions would be optimum for environmental reasons as well as suitability towards a range of functional groups. Once optimal conditions have been established, a series of 2-substituted succinic esters will be prepared from a range of boronic acids and a select group of dialkyl itaconate esters.

Once a route to racemic products has been identified, focus will be switched to developing an asymmetric version of this reaction. This will entail an investigation of key reaction parameters including a variety of rhodium salts, enantiopure ligands, organoboranes and additives. After a thorough optimisation a range of 2-substituted succinic esters will be prepared in both \((R)\)- and \((S)\)-configurations.
3.2 BACKGROUND

The synthetic usefulness of 2-substituted succinic esters can be demonstrated by looking at the synthesis of three major drugs, MMP inhibitors, lignan lactones and CNS drugs.

Matrix metalloproteinases (MMP’s) are a group of enzymes involved in the repair, degradation, and remodelling of extracellular matrix proteins in tissues. Since they have a destructive potential, failure to regulate MMP activity in physiological processes may lead to such problems as tissue destruction, and diabetic ulcers. UK-370, 106, 201, a potent and selective MMP-3 inhibitor discovered by chemists at Pfizer, has been developed as a candidate to treat pathological conditions, involving tissue destruction.
Chapter Three  
Rhodium-Catalysed Additions To Itaconate Esters

In the initial medicinal chemistry route 2-alkyl succinate derivative 205 (an intermediate within the synthesis of UK-307, 106) was prepared in six steps. Thomson et al.\textsuperscript{84} later reduced this to three steps through the use of an asymmetric hydrogenation of the alkene of 204 (Scheme 77). Biaryl bromide 202 was reacted with allyl alcohol under Jeffery's conditions to afford biarylpropanal, which was isolated in crystalline form as the sodium metabisulfite form 203. Phosphonosuccinate was then prepared from triethyl phosphonacetate and isolated in crystalline form. Treatment of the bisulfate and the phosphonosuccinate with an excess of potassium 'butoxide, led to cis-\(\beta\)-substituted itaconate 204 in around 61\% yield. This was followed by ruthenium catalysed asymmetric hydrogenation to produce (\(R\))-205 in a 65\% yield and 98\% ee.

\begin{scheme}
\begin{eqnarray*}
\text{202} & \xrightarrow{i} & \text{203} \\
& \xrightarrow{ii} & \\
& \xrightarrow{iii} & \text{204} \\
\end{eqnarray*}
\end{scheme}

i) allyl alcohol, Pd(OAc)$_2$, P(o-tolyl)$_3$, Bu$_4$NCl, NaHCO$_3$, MeCN, reflux; Na$_2$S$_2$O$_5$, MeOH, H$_2$O,  
ii) 'BuOK, 3-(Diethoxyphosphoryl)succinic acid 1-'Buty ester, 0\textdegree C;EtOAc, C$_6$H$_{14}$NH$_2$,  
iii) [(S)-BINAP-Ru-(\(p\)-cymene)Cl]Cl, MeOH, H$_2$O, H$_2$ (60psi), 60\textdegree C.

Scheme 77
Levy et al.\textsuperscript{85} also synthesised a range of MMP inhibitors in order to establish a connection between the structure and the activity of the compound. To do this they prepared a large quantity of intermediate 210 (Scheme 78). Maleic anhydride 206 was reacted with iso-butylene, and the resulting ene-adduct was reduced to 207 via catalytic hydrogenation. Subsequent methanolysis of the anhydride produced the mixture of regioisomers 208 and 209. Separation and resolution of the desired regioisomer 209 with (S)-methylbenzylamine yielded the final product 210. The undesired regioisomer 208 can be converted back into anhydride 207 via hydrolysis to the diacid followed by dehydration with acetic anhydride.

Scheme 78

Succinic acids have also been utilised in the preparation of (R)-(−)- and (S)-(+)−3-hydroxymethyl-l-tetralone tosylates 211, intermediates in the synthesis of new CNS drugs 212 and 213 (Scheme 79).
In this synthesis Raviña et al. produced 2-benzylsuccinic acid in only two steps via Stobbe condensation of benzaldehyde with dimethyl succinic acid followed by hydrogenation of the double bond leads to 2-benzylsuccinic acid 215 (Scheme 80). This then forms tetralonecarboxylic acid 216 through cyclisation in the presence of H₂SO₄ in a 50% overall yield.
Chapter Three  Rhodium-Catalysed Additions To Itaconate Esters

Lignan lactones such as deoxypodophyllotoxin 217 are known to show cytotoxic activities and can be utilised as anti-cancer drugs. Achiwa et al. synthesized a range of these compounds using the asymmetric form of the above route. A retrosynthesis of which is shown in Scheme 81.

Stobbe condensation of dimethyl itaconate and the required substituted benzaldehyde was followed by asymmetric hydrogenation of the alkene (Scheme 82). The asymmetric hydrogenation was carried out in methanol at 30°C for 40 hours under 1 atm. of H₂ in the presence of triethylamine using the neutral rhodium complex of (4S,5S)-MOD-DIOP 220. This is prepared by mixing [Rh(COD)Cl]₂ and MOD-DIOP in methanol. All reactions gave high optical purity (>93%ee) and quantitative yields. Optically pure (R)-arylmethylsuccinic acid monomethyl esters 219 were easily obtained by a single recrystallisation of the products from isopropyl ether.
One of the most common routes to 2-substituted succinic acids involves the synthesis of alkyldiene succinic acids followed by metal catalysed hydrogenation. Argade et al. obtained (E)-alkylidenedsuccinic acids via a general two-step synthesis utilizing Wittig methodology (Scheme 83). The reaction of maleimide 221 with triphenylphosphine (TPP) furnished the intermediate Wittig adduct 222, which in situ condensed with aliphatic aldehydes to afford the alkyldenedsuccinimides 223 in excellent yields. These afforded the (E)-alkylidenedsuccinic acids 224 on hydrolysis under reflux in a mixture of concentrated hydrochloric acid and glacial acetic acid (1:1) in quantitative yields.
Once the (E)-alkylidenedsuccinic acids have been formed, one of the simplest, and most common, methods for forming the chiral 2-substituted succinic acid is rhodium-catalysed asymmetric hydrogenation. There are many chiral ligands which successfully catalyse the asymmetric hydrogenation of the parent itaconic acid or its methyl ester. However, it is the hydrogenation of β-substituted itaconic acid derivatives that is of most interest. This normally presents a problem as Stobbe condensation yields a mixture of E and Z substrates. As these two substrates should show different enantioselectivities with the same ligand, and separation before hydrogenation is very difficult, a low enantioselectivity is often observed. (S,S)-Et-Duphos 227 was utilised by Burk et al. to complete the hydrogenation of β-itaconate 225 (3:1 E/Z ratio) to furnish 2-alkylsuccinate 226 in 97% ee (Scheme 84). Hydrogenation conditions of 0.03mol% [Rh(COD)(Et-Duphos)][BF₄], 10% NaOMe in methanol with 5.5 bar H₂ yielded a range of 2-alkylsuccinates in 97-99% ee. This was then improved on by the use of chiral ligand TangPhos 228 which also achieved 99% ee and greater for a range of 2-alkylsuccinates. β-itaconate 225 (3:1 E/Z ratio) was hydrogenated in the presence of 0.5mol% [Rh(TangPhos)(nbd)][SbF₆] in THF with 20psi H₂ to furnish 2-alkylsuccinate 226 in a 99% ee.

![Scheme 84](image-url)
PART A

3.3 AIMS AND OBJECTIVES

The object of this project was to produce a synthetic protocol for the production of 2-substituted succinic esters in one step from dimethyl itaconate ester, which would involve the rhodium-catalysed 1,4-addition of organoboranes.

3.4 BACKGROUND

In a previous study the Frost group revealed an efficient rhodium-catalysed conjugate addition of boronic acids to α,β-dehydroamino acid derivatives using only water as a solvent. 25 1-Naphthaleneboronic acid reacted with ethyl α-phthalimidoacrylate 43 in the presence of [Rh(COD)Cl]₂ in water (Scheme 85). It was remarkable that not only were no other additives required to give a 98% yield, but also the catalytic loading could be reduced to 0.5mol% with no loss in efficiency. It was also observed that not only electron-deficient and electron-rich arylboronic acids were efficient but also that aldehydes did not need protection. This is despite the fact that some rhodium catalysts promote addition reactions to aldehydes. Dehydroalanine derivative 44 was originally used but only gave a 30% yield due to intolerance of the aqueous conditions. This was overcome by the introduction of the phthalimide group, and along with esterification of the free acid group a stable substrate that could undergo 1,4-addition was formed. Both protecting groups can then be cleaved under acidic conditions (6NHCl/ AcOH, 4/1) to furnish the unnatural α-amino acid hydrochloride in good yields.
Chapter Three

Rhodium-Catalysed Additions To Itaconate Esters

Scheme 85

3.5 RHODIUM CATALYSED ADDITION OF BORONIC ACIDS TO DIMETHYLLITACONATE ESTERS.

3.5.1 Preliminary Studies

The reaction was first assessed using Hayashi conditions of [Rh(acac)(C₂H₄)₂]/(S)-BINAP in dioxane/water (10/1) at 100°C for 3 hours. This gave a disappointing yield of 26% (Scheme 86). However, once sodium fluoride was added this increased
to a gratifying 72%. Having established the ability of dimethyl itaconate to undergo 1,4-addition with arylboronic acids the investigation turned to examining aqueous conditions. Unfortunately the original aqueous conditions of Frost and Chapman proved inadequate giving an 8% yield. These conditions were then tested on a range of rhodium catalysts again to no avail with the highest yield being the 8% observed for [Rh(COD)Cl]$_2$, with no yield observed at all for the acac variants. Although there was evidence of some product formed with [Rh(C$_2$H$_4$)$_2$Cl]$_2$ the yield was too small to enable isolation. Thus whilst these yields are extremely low it has been confirmed that the 1,4 addition of arylboronic acids to dialkyl itaconate esters such as 200 can proceed in water.

**Table 10**
3.5.2 The introduction of SDS

During the preliminary investigation it was noted that dimethyl itaconate was only sparingly soluble in water even at elevated temperatures. Thus the addition of a phase transfer agent such as sodium dodecyl sulphate (SDS) was considered.

Lautens has already demonstrated that certain heteroaromatic alkenes can undergo 1,4-addition in water.\textsuperscript{37} The key to this reaction is the addition of the phase transfer agent SDS (Scheme 87). Here 2-vinylpyridine 230 reacted with 2.5 equivalents of phenylboronic acid in the presence of [Rh(COD)Cl\textsubscript{2}]/TPPDS, Na\textsubscript{2}CO\textsubscript{3} and SDS to afford the product 231 in an 84% yield.

\begin{equation}
\text{230} \xrightleftharpoons{[\text{Rh(COD)Cl}\textsubscript{2} (2\text{mol\%})]} \text{231, 84\% yield}
\end{equation}

Scheme 87

As with Lauten’s work, our rhodium-catalysed 1,4-addition benefited from the addition of SDS. 1-Naphthaleneboronic acid reacted with dimethyl itaconate in water in the presence of [Rh(COD)Cl\textsubscript{2}], Na\textsubscript{2}CO\textsubscript{3} and SDS to give a 79% yield of the succinate ester 232 in 16 hours.

The effects of the addition of both SDS and Na\textsubscript{2}CO\textsubscript{3} were then explored (Table 11). SDS proved crucial to the reaction even in the presence of two equivalents of Na\textsubscript{2}CO\textsubscript{3} if no SDS is added only a 9% yield is observed. It was noted that by increasing the equivalents of SDS the yield improves, but this then levels off after just over half an equivalent when dimethyl itaconate is completely solvated at 100°C. The presence of base is also vital for the full potential of the reaction to be achieved. When no Na\textsubscript{2}CO\textsubscript{3} is present the yield is almost halved to 55%. This again steadily increases, until it levels at around two equivalents. It is felt that a compromise is reached at two equivalents where the reaction is allowed to continue to its full capability but that the sensitivity of functional groups is not put in jeopardy by creating a very basic environment.

<sup>a</sup> Typical reaction conditions: Dimethyl itaconate, 1-napthaleneboronic acid (2 eq.), [Rh(COD)Cl]<sub>2</sub>, 1-napthaleneboronic acid (2 eq.), SDS, Na<sub>2</sub>CO<sub>3</sub>, water.

<sup>b</sup> isolated yield after flash chromatography.

Table 12

It is useful to note that although only a 15% yield of product is obtained at 40°C, the catalytic cycle is still able to proceed at this low temperature (Table 12). Hence, if a substrate was prone to decomposition at higher temperatures, an increased reaction time and a low temperature may be suitable. Generally as the temperature increases, side reactions can occur such as the hydroboration of the boronic acid to the corresponding phenol, so the overall isolated yield decreases. The optimum temperature was deemed to be 80°C where an 81% yield was produced after 16 hours. After 12 hours at this temperature it was shown that the reaction had reached...
completion. As there was no real decrease in yield between 12 and 16 hours, the most advantageous time for the reaction was set at 16 hours for convenience.

3.6 EXTENDING THE SCOPE

As a range of 2-substituted alkylsuccinic esters would be useful for the synthesis of new derivatives of MMP inhibitors and other drugs, an array of boronic acids were reacted with dimethylditaconate ester (Table 13). This examined the reactions sensitivity towards a range of functional groups as well as their electronic effects and steric constraints.

3.6.1 Range of Boronic Acids

It was gratifying to observe that a wide range of boronic acids were successfully applied to this reaction. There was no discrimination between electron-deficient and electron-rich boronic acids and varying of the substitution pattern of the aromatic ring (Table 13, entries 4, 5 and 6) demonstrated that steric effects had little consequence on yield. Dimethyl (para-methoxyphenyl)succinic ester 234 was produced in a 64% yield and its meta substituted counterpart 235 in a 67% yield. It was particularly interesting to note that the highest yield (78%) of the three was obtained at the most sterically challenging point with ortho. From a pharmacological point of view the success of the reactions of boronic acids incorporating functional groups such as acyl (-COMe), and nitro (-NO2) are very important as these groups provide convenient points for further modification. With the lowest yield obtained standing at 56%, this range of boronic acids showed that this reaction could successfully synthesise a large range of 2-substituted succinic esters in one step from commercially available starting materials.

^b isolated yield after flash chromatography.

The reaction of unsymmetrical esters would be a useful project as if the esters were orthogonally protected, there would be scope for further functionalisation as well as selective cleavage of the esters. This would make the esters and the 1,4 addition of boronic acids to them more attractive for complex synthetic routes.

### 3.6.2 The preparation of unsymmetrical esters

To obtain the unsymmetric esters the first step would be to selectively esterify the non-conjugated acid with an alcohol. It was found that esterification by stirring with the alcohol in question on a steam bath led to very low yield, even after 24 hours (Scheme 88). If the reaction was promoted by the addition of trimethylsilyl chloride, molecular sieves or magnesium sulfate a mixture of the mono and disubstituted products were obtained. The yield was improved by the use of itaconic anhydride 242, which was stirred on a steam bath in methanol for 3 days to produce a workable yield of 64% of mixed products. However, the isomers were produced in a 95:5 ratio (non-conjugated ester: conjugated ester), unfortunately the isomers were unseparable at this stage.
Ram and Charles developed a very simple and selective esterification for aliphatic carboxylic esters over conjugated or aromatic carboxylic acids (Scheme 89). The simple experiment involves heating to reflux the carboxylic acid in the alcohol of interest with 10% NiCl$_2$·6H$_2$O then extraction with ether or dichloromethane to give pure product in high yields with no need for further purification. The authors put this success down to Ni(II) acting as a mild and selective catalyst due to a suitable balance between its hard and soft acid characters. A range of carboxylic acids were tested and gave high yields for aliphatic carboxylic acids. Mixtures of aliphatic and aromatic acids provided only the esterified aliphatic carboxylic acid products. Finally, itaconic acid was examined and produced a significant 86% non conjugated mono ester and 6% diester with no conjugated monoester detected (Scheme 89). The monosubstituted and disubstituted products were then easily separated in work up.
This methodology was then exploited to produce two mono non-conjugated esters of itaconic acid (Table 14). Isolation of the desired monoester was performed by washing the aqueous solution with ether to remove any diester. Acidification of the Na$_2$CO$_3$ aqueous layer followed by ether extraction furnished the mono esters, which could be used without further purification. Moderate yields of all non-conjugated mono esters were obtained with no traces of their conjugated counterparts.

Typical Reaction Conditions: Dimethyl itaconate (0.01mol), NiCl$_2$·6H$_2$O (10mol%), and alcohol (10ml) at reflux.

Table 14

Esterification of the second acid proved problematic as too harsh a method led to degradation of the product. Several esterification processes were tried which finally led to two workable methods (Table 15). EDCI coupling led to a 24% yield and a more gentle acid catalysed esterification led to a 20% yield of 244. These two alternative methods provide a degree of flexibility as one method may be more suited to certain alcohols or acids.
Using the EDCI methodology, two different unsymmetrical esters were obtained in moderate to low yields (Table 16).

Table 17
3.6.3 1,4 Addition Of 1-Napthaleneboronic Acids To Esters

Due to time constraints and only small quantities of each of the unsymmetrical esters and new symmetrical esters being available only two esters were examined in the rhodium-catalysed 1,4-addition reaction. Addition of 1-napthaleneboronic acid to 1-benzyl-4-methyl 2-methylenesuccininate gave a pleasing 72% yield of addition product 247, with ester 246 yielding 49% of addition product 248 (Scheme 90). These promising results indicate that the addition of other mixed esters would be viable under these conditions. It should be noted that no evidence of ester cleavage was observed.

3.7 CONCLUSION

A novel one step route to 2-alkylsuccin esters from dialkylitaconic esters has been established. The use of SDS provided the means for the reaction to take place in water thus increased its capabilities in organic synthesis. There is still much more potential for this reaction to be explored but this initial study has shown the method’s high tolerance of functional groups and highlighted the possibilities when used in conjunction with unsymmetrical esters.
PART B

3.8 AIMS AND OBJECTIVES

The objective was to synthesis a range of 2-substituted succinic esters through the rhodium catalysed asymmetric 1,4-addition of boronic reagents to itaconate ester derivatives (Scheme 91). Although asymmetric 1,4-additions have been successfully applied to a range of activated alkenes, there are few reports of α-substituted activated alkenes being utilised. This can be attributed to their lower reactivity and crucially, in the asymmetric process, the enantioselectivity is determined at the point of hydrolysis of the oxa-π-allylrhodium intermediate 249 and not at the insertion step (Scheme 92).
3.9 RHODIUM CATALYSED ASYMMETRIC 1,4-ADDITION OF ORGANOBORON REAGENTS TO DIMETHYL ITACONATE

3.9.1 Preliminary Results

Initial experiments focused on the continuation of the previous study of the racemic reaction. Thus phenylboronic acid was added to dimethyl itaconate in a solution of water, SDS and Na$_2$CO$_3$ in the presence of [Rh(COD)Cl]$_2$/(R)-BINAP (Scheme 93). This gave 229 in good yield, 65%, however, the enantioselectivity was disappointingly low at 23%ee determined by HPLC analysis. An assay was compiled using a Daicel Chiralcel OD column at ambient temperature and a 98:2 Hexane:IPA solvent system with a flow rate of 1 mL/min. Two clean peaks were found at retention times of 19.0 and 28.9 minutes. The first enantiomer's absolute configuration was determined to be the (R)-isomer by comparison with known data for dimethyl 2-benzylsuccinate.

![Scheme 93](image)

Hayashi's conditions of 3mol% [Rh(acac)(C$_2$H$_4$)$_2$] and 3.3mol%(S)-BINAP in dioxane/H$_2$O (10/1) solution with phenylboronic acid (5 equiv.) and dimethyl itaconate (1 equiv.) at 100°C for 18 hours also afforded a high yield of 72% of 229, but again low enantioselectivity (<5% ee).  

It is known that potassium (organo)trifluoroborate salts offer possible advantages in terms of reactivity and selectivity for many rhodium-catalysed 1,4-addition reactions. This is exemplified by the addition of potassium trifluoroorganoborates to crotonamides. Potassium phenyltrifluoroborate reacted
Chapter Three  

Rhodium-Catalysed Additions To Itaconate Esters

with crotonamide 48 in the presence of [Rh(COD)₂][PF₆] and (R)-BINAP in toluene/water (4/1) at 100°C to furnish 49 in 86% yield and 93% ee (Scheme 94). Genet observed that under these conditions potassium trifluoroborates have fully reacted after 1 hour but boronic acids reached only 62% after 1 hour and 40 minutes. This is thought to be the maximum yield as the remainder of the boronic acid has been used up through protonolysis after transmetallation.

& \quad \text{93% ee}
\end{align*}
\]

Scheme 94

The selectivity and reactivity of phenylboronic acid compared with commercially available potassium trifluorophenylborate was therefore compared with a range of rhodium catalysts. Both neutral and cationic catalysts were examined with both potassium trifluorophenylborate and phenylboronic acid. The conditions chosen for this study were dioxane/water (10/1) at 110°C for 18 hours (Table 18). The best yields for each catalyst were obtained with phenylboronic acid under these conditions (Table 18, entries 1, 3 & 5). However the highest enantioselectivity achieved when using phenylboronic acid was a mere 23% (entry 3). However, whilst the yields with the potassium trifluorophenylborate were lower, a promising 43% ee was obtained in combination with the cationic rhodium species [Rh(COD)₂][PF₆] in 64% yield. The combination of a neutral catalyst with potassium trifluorophenylborate salt was unsuccessful with barely detectable enantioselectivity with either catalyst (entries 1 & 3).

### 3.9.2 In Depth Catalyst study

To gain a full insight into the mechanism and the actual active catalyst several parameters were explored. As a better understanding of the catalyst is gained a new catalyst capable of greater enantioselectivity and reactivity may be found. For each of these studies potassium trifluoro(l-naphthyl)borate was used to make dimethyl 1-naphthylsuccinate, a colourless crystalline solid, easily purified by crystallisation giving a well-separated HPLC trace. Potassium trifluoro(l-naphthyl)borate 251 was
obtained a high yield in accordance with a literature procedure from naphthalene boronic acid 250 and potassium difluorohydride (Scheme 95).

\end{align*}
\]

Scheme 95

The first of these small studies examine a variety of bisphosphine ligands and their effect on enantioselectivity.

### 3.9.3 Ligand study

A range of bisphosphine ligands were examined within the reaction all in a 2:1 ratio (ligand:rhodium). As BINAP 55 is well documented as a suitable ligand for rhodium-catalysed 1,4-additions to activated alkenes it was unsurprising that it obtained the highest ee at 64% (Scheme 96). A binaphthyl basis to the ligand seemed to work well with Tol-BINAP 252 making a modest 42% ee although the diphosphite, Pringles ligand, 45 was disappointing with a low 11% ee recorded. Chiraphos 8, Norphos 253 and Duphos 227 all provided low enantioselectivity with Norphos 253 performing best with 30% ee. Phanephos 254 and DIOP 5 both achieved good yields but again disappointingly low ees (Scheme 96).
Having established (R)-BINAP 246 as the most selective ligand the cationic rhodium catalyst [Rh(COD)((R)-BINAP)][PF₆] was preformed to establish if this is the active
catalyst (Table 17). Treatment of dimethylitaconate with potassium trifluoroor(1-naphthyl)borate in the presence of 3mol% of preformed catalyst \([\text{Rh(COD)}((R)-\text{BINAP})][\text{PF}_6]\) in toluene/water (20:1) at 110°C for 18 hours affords 232 in an outstanding 72% yield but surprisingly with no enantioselectivity. Interestingly, the addition of one equivalent (to Rh.) of free chiral ligand \((R)-\text{BINAP}\) to the reaction afforded the addition product with good enantioselectivity (78%ee), but with disappointing reactivity leading to only a 25% yield. It is feasible that the excess ligand could block the free coordination sites on the rhodium, thus, affecting the enantioselective protonation. It was considered that forming the catalyst in situ from \([\text{Rh(COD)}_2][\text{PF}_6]\) and BINAP provided the best compromise between enantioselectivity and yield. Thus it was this catalyst system which was chosen for further optimisation studies.

**Table 19**
### 3.9.4 Temperature Study

Often an elevated temperature is required in transition metal catalysis to form the active species in the reaction, or to enable the catalyst to turnover. This appears to be the case here as no reaction is observed at room temperature. However at 60°C the catalyst yielded 42% of the addition product, interestingly, with no enantioselectivity (Table 20). This is analogous to the product formed when preformed catalyst [Rh(COD)((R)-BINAP)][PF₆] was used without the addition of a second equivalent of (R)-BINAP. Whilst the yield here is lower but this can be attributed to the lower temperature affecting the reactivity of the catalyst.

3.9.5 Solvent Study

To investigate whether the enantioselectivity and yield could be further increased, a solvent study was carried out. Using the preferred reaction conditions, treatment of dimethylitaconate with potassium trifluoro(1-naphthyl)borate in the presence of 3mol% \( [\text{Rh(COD)}_2][\text{PF}_6] \) and \((R)\)-BINAP in a solvent/water (20/1) solution at 110°C for 18 hours gave the 2-substituted succinic ester 232 in a range of yields.

The enantioselectivity and yields obtained proved to be highly dependent on the solvent used (Table 21). Generally, very low enantioselectivity was obtained in polar solvents. For example, when the reaction was performed in acetonitrile a racemic product was obtained in moderate yield. The highest yield (87%) was obtained using dioxane, however whilst the yield was high, only a moderate enantioselectivity (42%ee) was obtained. The use of benzotrifluoride, dichloroethane and hexane also gave moderate enantioselectivity and yields.

The highest enantioselectivities were achieved in aprotic, non-chelating solvents such as toluene and benzene. Interestingly, the highest ee was achieved when the reaction was performed in benzene, whereby the substituted succinic ester 232 was obtained in 56% yield and 82% ee. This is in contrast to the majority of other rhodium catalysed asymmetric 1,4-addition reactions which favour toluene and dioxane.

Table 21

3.9.6 Proton Source Study

During our research Genet²⁷ reported the asymmetric synthesis of alanine derivatives utilising rhodium-catalysed 1,4-addition. Potassium trifluorophenylborate was added to methyl-2-acetylamidoacrylate 41 in the presence of \([\text{Rh(COD)}_2][\text{PF}_6]\) and \((S)-\text{BINAP}\) in toluene/water (10/1) to yield 46 in quantitative yield but only 28% ee (Scheme 97). Genet and co-workers subsequently investigated a range of proton
sources based on phenol were then tested in anhydrous conditions. The range of enantioselectivities found demonstrated the significance of the proton source in reactions, whereby the enantioselectivity is determined in the protonation step. Guaiacol proved to be the best proton source with an 83% ee being accomplished (Scheme 97).

\[
\begin{align*}
\text{Proton Source} & : \text{H}_2\text{O} \quad \text{quant. yield} \quad <28\% \text{ e.e.} \\
& : \text{Guaiacol} \quad 91\% \text{ yield} \quad 83\% \text{ e.e.}
\end{align*}
\]

Scheme 97

Following this, addition of potassium trifluoro(l-naphthyl)borate to dimethyl itaconate in the presence of cationic rhodium complex prepared in situ from \([\text{Rh(COD)}_2][\text{PF}_6]\) and (S)-BINAP in toluene at 110°C using a range of protonating agents based on phenol were examined (Table 22).

\[
\begin{align*}
\text{KOH, DMSO} \\
\text{Scheme 98}
\end{align*}
\]

All proton sources used are commercially available, with the exception of 2-isopropoxyphenol 257, which was prepared in accordance to literature procedure. Addition of 2-chloropropane to a stirred solution of catechol and potassium hydroxide in DMSO afforded the desired phenol in 20% yield (Scheme 98).

When phenol (261) was used as the protonating agent, the addition product was obtained in an excellent yield (100%) but with disappointing enantioselectivity (12%ee). We envisaged the use of phenols with greater steric bulk might force the
protonation to occur from one face preferentially, thus, the use of more sterically hindered proton sources was investigated. Quantitative yields and more significant enantioselectivities were achieved with a range of ortho-substituted phenols. It appeared that the enantioselectivity is highly dependant upon the protonating phenol and by increasing steric bulk in the ortho-position a decrease in the enantioselectivity is realised. This is contrary to Genet's observations for the addition to methyl 2-acetylamidoacrylate 49. It appeared that the highest enantioselectivities were obtained using proton sources with the ability to chelate to the rhodium. The use of non-complexing 1-bromophenol 260, gave an almost racemic product, but in excellent yield whereas 2-isopropanolphenol 257 and 2-methoxyphenol 258 gave much higher selectivity but in moderate yield. Although it is difficult to rationalise the relation between the level of enantioselectivity and the electronic nature of the ortho substituents, the highest ee value was obtained using 2-methoxyphenol (guaiacol) 258 which gave the desired product in 56% yield with 60%ee. However this is still only comparable to the use of water as the protonating agent which also gave the addition product with 60% ee also, but slightly lower yield of 45%.

*Table 22*
3.10 CONCLUSION

Whilst many of the results recorded in trying to identify a more efficient and enantioselective system, have gone on to confuse the situation we have drawn some worthwhile conclusions from our efforts:

- The application of cationic rhodium catalysts in conjunction with potassium trifluoroorganoborate salts affords both higher chemical yields and enantioselectivities.
- Preforming the rhodium-ligand catalyst by adding a further equivalent of ligand (to rhodium) to the reaction mixture provides higher enantioselectivities, but reduced chemical yields when compared to forming the catalyst in situ.
- BINAP is the current ligand of choice for this reaction.
- An elevated temperature is essential for the reaction to proceed enantioselectively.
- Aromatic alcohols can be used as proton sources, however the best do not provide an enhancement in enantioselectivity over that achieved with water.
- The use of aromatic solvents as the core solvent provides the greatest selectivity.

Thus the optimal conditions for these reactions is to heat the benzene solution of the BF₃K salt (2 equiv.), itaconate ester (1 equiv.) and water (1 equiv.) at 110°C in the presence of [Rh(COD)₂][PF₆]/BINAP (1:2). With these conditions in hand we set about the synthesis of a variety of 2-substituted succinic esters through the addition of potassium organotrifluoroborate salts to dimethyl itaconate.

3.11 EXTENDING THE SCOPE

Whilst there are a number of commercially available organoboronic acids exhibiting a variety of functional groups, in comparison very few organo potassium trifluoroborate salts are available. However, the conversion of aryl boronic acids to their potassium trifluoroborate equivalents is a simple high yielding process.

*a Reaction Conditions: Organoboronic acid (1.2 mmol), methanol (3 mL), KHF$_2$ (4 mmol), rt, 10 minutes.

**Table 23**

As described previously by Vedejs, treatment of commercially available arylboronic acids with aqueous KHF$_2$ resulted in precipitation of the potassium salts.
After the addition of KHF$_2$ the solvents were removed in vacuo and the remaining solid was extracted with acetone. Other salts (KBF$_4$, KF etc.) are insoluble in acetone hence on removal of the solvent from extracts pure salt was obtained. **Caution: HF is a possible side product from this reaction and so the appropriate care should be taken when handling the reaction medium.**

Through this method an array of BF$_3$K salts were prepared in high yields (Table 23). It was interesting to note that even though the KHF$_2$ was strong enough to etch any glassware used there was only a slight drop in yield of product in the presence of some functional groups (Table 23, entries 2, 3, 5 & 6).

### 3.11.2 1,4-addition of Potassium Trifluoro(organo)borates

The study of the range of potassium trifluoro(organo)borates in the rhodium catalysed 1,4-addition was undertaken in collaboration with Rebecca Moss. In all but one case the 2-substituted succinic esters were produced in excellent yields with significant and consistent enantioselectivity. Both electron-rich and electron-deficient potassium trifluoro(organo)borates were successfully coupled (Table 24). The absolute configuration of the 1,4-addition products were assigned by comparison of the retention time of the previously assigned enantiomers using chiral HPLC. Using (R)- or (S)-BINAP allowed the formation of (R)- or (S)- 1,4-addition products with (R)-BINAP giving (R) configuration of the product. This is consistent with α-re face protonation of the oxa-π-allyl rhodium intermediate (Chapter 1).

Potassium trifluorophenylborate achieved the highest enantioselectivity affording 51% yield of 2-benzylsuccinic dimethyl ester in 68%ee. It should be noted that only trace amounts of the ortho-methoxy phenyl product was observed, this is attributed to steric hinderance. In contrast to this para-methoxy phenyl achieved a high yield of 89-93% and moderate selectivity of 62% ee. Through comparison of para-methoxy with para-acetyl it can be seen that an electron-donating group in the 4-position enhances the enantioselectivity whereby an electron-withdrawing group detracts. It is pleasing to note that there is very little difference in selectivity between meta and para substituted substrates.

\textsuperscript{a} Reaction Conditions: dimethyl itaconate (0.25mmol), potassium trifluoro(organoborate (0.05mmol), [Rh(COD)\textsubscript{2}][PF\textsubscript{6}] (3mol%), BINAP (6.6mol%), benzene (2ml), water (0.25mmol), 18 hours.

\textsuperscript{b} isolated yields after flash chromatography.

\textsuperscript{c} determined by HPLC analysis using chiral column (Chiral OD-H (98:2) Hexane:2-PrOH)

Table 24
3.12 Conclusion

Despite the wide range of asymmetric 1,4-addition reactions accomplished the asymmetric 1,4-addition to dimethylitaconate is by no means trivial. This is attributed to the fact that when dealing with 1,1-disubstituted substrates the enantioselectivity is determined in the hydrolysis step of the oxa-π-allylrhodium intermediate and not during the insertion step as is the case with most 1,4-addition reactions.\textsuperscript{99}

The mechanism for 1,4-addition is explained in detail in section 1.3 of the literature review. Briefly it consists of the formation of the active \([\text{Rh(OH)}]\) catalyst followed by transmetallation of the aryl group between boron and rhodium. Coordination of the alkene is followed by insertion and finally protonolysis to form the product and regenerate the active catalyst (Scheme 99).

![Scheme 99](image)

For additions to 1,2-disubstituted alkenes the chiral centre is formed at the insertion step, thus the coordination of the alkene to the rhodium directly affects the configuration of newly formed chiral centre. The stereochemical pathway of the
mechanism demonstrates how the ligand determines which face the alkene coordinates (Scheme 100).

BINAP has been extensively studied and so the skewed structure of 279 is known to reflect its interaction with transition metals. It can be seen that (S)-BINAP rhodium intermediate 279 has a free space in the lower part of the coordination site. The upper part being blocked by one of the phenyl rings of the BINAP ligand. This forces the alkene of cyclohexenone to coordinate through its α-si face rather than its α-re face. Migratory insertion then creates a stereocentre in 280 with absolute configuration (S). This model can be used to predict a host of 1,4-addition products configuration with the (S)-BINAP rhodium intermediate always attacking the α-si face of the α,β-unsaturated carbonyl.

The situation is complicated further when the protonolysis occurs to form a new chiral centre. For example Hayashi reported that organoboronic acids react with α-
substituted nitroalkenes to form the *cis* isomer in high enantioselectivity. As shown in Scheme 101 phenylboronic acid (5 equiv.) reacts with 1-nitrocyclohexene 281 in the presence of [Rh(acac)(C₂H₄)₂]/(S)-BINAP catalyst at 100°C for 3 hours in dioxane/water (10/1) to give 282 in an 89% yield. Both the *cis* and *trans* diastereoisomers were pure with 98%ee but they appeared in an 87/13 *cis/trans* ratio.

It is interesting to note that not only is the *cis* isomer the main product but that this can be converted to the thermodynamically more stable *trans* product simply by refluxing with sodium carbonate with no loss in enantioselectivity. A range of boronic acids reacted well with 1-nitrocyclohexene to produce high yields of 85% *cis* product with between 90-97%ee for both *cis* and *trans* isomers. Unfortunately this reaction does require five equivalents of arylboronic acid due to the elevated temperature so is less economically than would be desired.

![Scheme 101](image)

The origin of the enantioselectivity and the formation of the *cis* product here can be explained by looking at both the mechanism and the stereochemical pathway (Scheme 102).

As with α,β-unsaturated carbonyls transmetallation is followed by coordination of the alkene, then insertion. The same stereochemical model can be used to show that the aryl group will be in the *(S)* configuration if *(S)*-BINAP is used, as the nitro group will occupy the vacant lower quadrant of the catalyst. However, another stereocentre is formed during the protonolysis step. Equatorial protonation results in the formation of the *cis* product and axial protonation the *trans*. Equitorial protonation is favoured due to approach from the less hindered face, thus formation of the *cis* product predominates. The thermodynamically more stable *trans* product
can be formed by reflux in ethanol in the presence of sodium carbonate. As both the cis and the trans products are formed in 98% enantiomeric purity, it can be seen that the first stereocentre to be generated is fixed.

Scheme 102

Dimethyl itaconate and other 1,1-disubstituted substrates are even more complicated. This is due to the chiral centre not being directly formed directly at the insertion step. Furthermore due to the similar bulk of both substituents on the alkene it is free to coordinate from either the α-si or the α-re face (Scheme 103). The protonation step then forms the chiral centre. This could either happen via internal protonation from the already coordinated proton source in a syn fashion; or the proton source does not coordinate and protonation occurs from the opposite face to rhodium forming the anti product.

Formation of product C could occur via:

- Coordination through the α-re face leading to formation of A. Followed by internal syn protonation.
- Coordination through the α-si face leading to formation of B. Followed by external anti protonation.
Formation of product D could occur via:

- Coordination through the α-si face leading to formation of B.
  Followed by internal syn protonation.

- Coordination through the α-re face leading to formation of A.
  Followed by external anti protonation.

To further complicate matters it is not known whether the two possible oxa-π-allyl intermediates A and B can interconvert with each other.

If intermediates A and B can interconvert then only racemic product would be produced. As moderate enantioselectivity was achieved this is not the case. However, when [Rh(COD)₂][PF₆] with one equivalent of BINAP or [Rh(COD)(BINAP)][PF₆] with no added BINAP is used racemic products are formed. This could indicate that the extra equivalent of BINAP prevents this interconversion or that it is unable to block one method of protonation at low temperature. The formation of a racemic mixture when the reaction proceeds at 80°C also supports the theory.

The success of both water and guaiacol as proton sources over phenol and 2-bromophenol suggest that the mechanism proceeds through internal protonation as both of these will coordinate better with the metal centre.

Although extensive further investigation is required I would predict that the mechanism proceeds through a high-energy complex consisting of two equivalents of BINAP forcing the alkene to coordinate through its α-re face followed by internal protonation to produce (S)-configuration of the product.
Chapter Three  

Rhodium-Catalysed Additions To Itaconate Esters

Scheme 103
CHAPTER FOUR:

*Experimental*
4 EXPERIMENTAL

General Considerations

Commercially available solvents and reagents were obtained from Sigma-Aldrich Company Ltd, Lancaster Synthesis Ltd, Fisher Scientific Ltd and Strem Chemicals UK and were used without further purification, apart from the following: dichloromethane and acetonitrile were distilled from calcium hydride, whilst toluene, tetrahydrofuran, hexane and diethyl ether were distilled from sodium. Solvents and reagents were deoxygenated where necessary by purging with nitrogen. 'Petrol' refers to the fraction of petroleum ether boiling in the range of 40-60°C.

Analytical thin layer chromatography (TLC) was performed using commercially available aluminium backed plates coated with Merck Kieselgel 60 0.20mm (ALUGRAM® sil G/UV_{254}) and visualised under ultra-violet light (at 254nm), or by staining with potassium permanganate, vanillin or ninhydrin solution. Flash column chromatography was carried out using Merck Kieselgel 60 H silica gel (particle size: 0.063-0.100mm)

Melting points were determined using a Büchi 535 melting point apparatus and are uncorrected. Infra red spectra (4000 to 600cm\(^{-1}\)) were recorded on a Perkin Elmer (1600) FT spectrometer with internal calibration. Elemental analyses were performed with an Exeter analytical, INC. CE-440 elemental analyser in the Chemistry Department at the University of Bath. Fast Atom Bombardment (FAB) and Electron Impact (EI) mss spectra were obtained using a Fisons VG autospec Finnigan MAT 8340 instrument at the University of Bath.

\(^1\)H, \(^{13}\)C and \(^{11}\)B NMR spectra were recorded on a Joel EX-400, Brüker DPX-300 or a Joel GX-270 spectrometer. Chemical shifts (\(\delta\)) are expresses in parts per million (ppm), referenced to an internal SiMe\(_4\) standard for \(^1\)H-NMR, and relative to solvent for \(^{13}\)C-NMR and \(^{11}\)B-NMR. The multiplicities of the spectroscopic data are presented in the following manner: singlet (s), broad singlet (br s), doublet (d), doublet of doublets (dd), triplet (t), quartet (q), and multiplet (m). Coupling constants (\(J\)) are expressed in Hertz (Hz). The assignment of aromatic proton
resonances for para disubstituted benzene rings has been simplified by assuming an AB system, however the characteristic features of an AA’BB’ system were observed in the NMR spectra.

High Performance Liquid Chromatography (HPLC) was performed on TSP Thermo Separation Product Spectra series system, which uses chiral columns such as Chiralpak OD-H by Daicel Chemical Ind. Ltd.
4.1 PREPARATION OF KETONES VIA THE RHODIUM-CATALYSED ADDITION OF ARYLBORONIC ACIDS TO ANHYDRIDES

General Procedure

\[
\text{ArB(OH)}_2 + \text{[RhCl(C}_2\text{H}_4\text{)]}_2 \xrightarrow{\text{1,4-dioxane, 65°C, 16h}} \text{Ar}\text{C} = \text{O}
\]

To a pressure-tube charged with \([\text{RhCl(C}_2\text{H}_4\text{)]}_2\) \((0.01\text{g}, 0.024 \text{ mmol, 1.5 mol%})\) was added 1,4-dioxane \((6 \text{ mL})\), boronic acid \((2.24 \text{ mmol, 1.4 equiv.})\) and anhydride \((1.6 \text{ mmol})\). The tube was sealed, placed in a cold oil bath which, then heated to 65°C and stirred for 16 hours. The mixture was allowed to cool to room temperature and diluted with water \((10 \text{ mL})\) and the product extracted into ethyl acetate \((3 \times 10 \text{ mL})\), the combined extracts were washed with brine \((3 \times 10 \text{ mL})\), dried over magnesium sulphate and concentrated in vacuo. The crude product was then purified by flash column chromatography (ethyl acetate:hexane, 1:8 by volume) to afford the desired aryl ketone.
Acetophenone (170)

Acetic anhydride (0.163 g, 1.6 mmol) and phenylboronic acid (0.273 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless oil (0.167 g, 87% yield); \( R_f \) (petrol:ethyl acetate 8:1) 0.36; \( \nu_{\text{max}} \) (KBr/Nujol)/cm\(^{-1}\) 1730 (C=O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 7.8 - 7.9 (2H, m, Ar), 7.3 - 7.5 (3H, m, Ar), 2.50 (3H, s, CH\(_3\)); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 198.3, 137.4, 133.4, 128.9, 128.6, 26.9. Data identical to those in literature\(^{106}\).

Benzophenone (180)

Benzoic anhydride (0.362 g, 1.6 mmol) and phenylboronic acid (0.273 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless crystalline solid (0.22 g, 76% yield) mp (hexane) 50-51°C; \( R_f \) (Petrol: ethyl acetate 12:1) 0.39; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1655 (C=O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 7.9 - 7.8 (4H, m, Ar), 7.6 - 7.5 (2H, m, Ar), 7.5 - 7.3 (2H, m, Ar); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 197.1, 138.0, 132.8, 130.5, 128.7. Data identical to those in literature\(^{115}\).
1-(3-Nitrophenyl)ethanone (181)

Acetic anhydride (0.163 g, 1.6 mmol) and 3-nitrophenylboronic acid (0.374 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a pale yellow solid (0.148 g, 56% yield), mp 75-77°C; R_f (petrol:ethyl acetate 8:1) 0.47; ν_max (Nujol)/cm⁻¹ 1690 (C=O); δ_H (300 MHz; CDCl₃) 8.8-8.9 (1H, m, Ar), 8.3 - 8.5 (3H, m, Ar); δ_C (75.5 MHz; CDCl₃) 195.6, 148.4, 138.2, 133.7, 129.8, 127.3, 123.1, 26.6. Data identical to those in literature.¹⁰⁷

1-m-Tolylethanone (182)

Acetic anhydride (0.163 g, 1.6 mmol) and 3-methylphenylboronic acid (0.305 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.146 g, 68% yield); R_f (petrol:ethyl acetate 8:1) 0.43; ν_max (Nujol)/cm⁻¹ 1675 (C=O); δ_H (300 MHz; CDCl₃) 7.7-7.6 (2H, m, Ar), 7.3-7.1 (2H, m, Ar), 2.46 (3H, s, CH₃), 2.82 (3H, s, CH₃); δ_C (75.5 MHz; CDCl₃) 198.9, 138.7, 137.5, 134.2, 129.2, 128.8, 125.9, 27.0, 21.7. Data identical to those in literature.¹⁰⁸
1-(4-Methoxyphenyl)ethanone (183)

Acetic anhydride (0.163 g, 1.6 mmol) and 4-methoxyphenylboronic acid (0.340 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless solid (0.161 g, 67% yield) mp (hexane) 38-39°C; Rf (Petrol: ethyl acetate 8:1) 0.33; v_max (Nujol)/cm⁻¹ 2850 (OCH₃), 1665 (C=O); δ_H (300 MHz; CDCl₃) 7.93 (2H, d, J 8.6 Hz, Ar), 6.92 (2H, d, J 8.6 Hz, Ar), 3.86 (3H, s, OCH₃), 2.55 (3H, s, CH₃); δ_C (75.5 MHz; CDCl₃) 197.1, 163.9, 131.0, 130.7, 112.1, 55.8, 26.7. Data identical to those in literature.¹¹³

1-(3-Methoxyphenyl)ethanone (184)

Acetic anhydride (0.163 g, 1.6 mmol) and 3-methoxyphenylboronic acid (0.340 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.17 g, 69% yield); Rf (petrol:ethyl acetate 8:1) 0.32; v_max (Nujol)/cm⁻¹ 2837 (OCH₃), 1691 (C=O); δ_H (300 MHz; CDCl₃) 7.44 (2H, t, J 8.9 Hz, Ar), 7.28 (1H, t, J 8.9 Hz, Ar), 7.1-7.0 (1H, m, Ar), 3.75 (3H, s, OCH₃), 2.50 (3H, s, CH₃); δ_C (75.5 MHz; CDCl₃) 197.6, 159.6, 138.3, 128.9, 120.9, 119.5, 112.2, 55.4, 26.8. Data identical to those in literature.¹¹³
1-(Naphthalen-4-yl)ethanone (185)

Acetic anhydride (0.163 g, 1.6 mmol) and 1-naphthaleneboronic acid (0.385 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless oil (0.21 g, 76% yield); \( R_f \) (petrol:ethyl acetate 8:1) 0.30; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1680 (C=O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 8.80 (1H, d, \( J=8.5 \) Hz, Ar), 8.0 – 7.9 (3H, m, Ar), 7.6 – 7.5 (3H, m, Ar), 2.73 (3H, s, CH\(_3\)); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 202.2, 135.8, 134.4, 133.4, 130.6, 129.2, 128.9, 128.2, 127.1, 126.9, 126.5, 30.9. Data identical to those in literature.\(^{114}\)

1,4-Diacetylbenzene (186)

Acetic anhydride (0.163 g, 1.6 mmol) and 4-acetylphenylboronic acid (0.367 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless crystalline solid (0.223 g, 86% yield); mp 112-114°C; \( R_f \) (petrol:ethyl acetate 8:1) 0.51; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1692 (C=O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 8.00 (4H, s, Ar), 2.65 (3H, s, CH\(_3\)); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 197.5, 140.2, 129.3, 27.1. Data identical to those in literature.\(^{116}\)
4.2 PREPARATION OF KETONES VIA THE RHODIUM-CATALYSED ADDITION OF ARYLBORONIC ACIDS TO N-HYDROXYSUCCINIMIDE (NHS) ESTERS

General Procedure

To a Pressure tube charged with $[\text{RhCl(C}_2\text{H}_4\text{)}_2]_2$ (0.024 mmol, 1.5 mol%) was added 1,4-dioxane (6 mL), boronic acid (2.24 mmol, 1.4 equiv.) and the NHS ester (1.6 mmol). The tube was sealed, placed in a cold oil bath, then heated to 65°C and stirred for 16 hours. The mixture was allowed to cool to room temperature and diluted with water (10 mL) and the product extracted into ethyl acetate (3 x 10 mL), the combined extracts were washed with brine (3 x 10 mL), dried over magnesium sulphate and concentrated in vacuo. The crude product was then purified by flash column chromatography (ethyl acetate:petrol, 1:8 by volume) to afford the desired aryl ketone.
Chapter Four

**Benzophenone (180)**

1-Benzoylpyrrolidine-2,5-dione (0.325 g, 1.6 mmol) and phenylboronic acid (0.273 g, 2.24 mmol), were reacted under the standard protocol to generate the desired compound as a colourless crystalline solid (0.18 g, 64% yield) mp (hexane) 50-51°C; Rf (petrol:ethyl acetate 12:1) 0.39; νmax (Nujol)/cm−1 1655 (C=O); δH (300 MHz; CDCl3) 7.79 (4H, m, Ar), 7.57 (2H, m, Ar), 7.46 (2H, m, Ar); δC (75.5 MHz; CDCl3) 197.1, 138.0, 132.8, 130.5, 128.7. Data identical to those in literature.115

**Propiophenone (198)**

1-Propionylpyrrolidine-2,5-dione (0.248 g, 1.6 mmol) and phenylboronic acid (0.273 g, 2.24 mmol), were reacted under the standard protocol to generate the desired ketone as a colourless oil (0.09 g, 43% yield); Rf (petrol:ethyl acetate 4:1) 0.48; νmax (Nujol)/cm−1 1655 (C=O); δH (300 MHz; CDCl3) 7.94 (2H, d, J 7.2 Hz, Ar), 7.5 – 7.4 (3H, m, Ar), 2.96 (2H, q, J 7.2 Hz, CH2), 1.20 (3H, t, J 7.2 Hz, CH3); δC (75.5 MHz; CDCl3) 201.1, 137.3, 133.2, 129.2, 128.9, 128.7, 128.5, 32.1. Data identical to those in literature.111
4.3 RHODIUM-CATALYSED ADDITION OF ARYLBORONIC ACIDS TO ITACONATE ESTERS IN WATER.

**General Procedure**

![Chemical reaction diagram]

To a solution of [RhCl(COD)]$_2$ (0.012 g, 0.058 mmol, 2 mol%) in water (6.6 mL) was added dimethyl itaconate (0.21 g, 1.308 mmol), boronic acid (3.36 mmol, 2.5 equiv.), sodium dodecyl sulphate (0.189 g, 0.684 mmol, 0.5 equiv.) and sodium carbonate (0.291 g, 3.648 mmol, 2 equiv.). The resulting solution was stirred at 80°C for 16 hours. The mixture was allowed to cool to room temperature the product extracted with diethyl ether (3 x 15 mL), the combined extracts were washed with brine (3 x 15 mL), dried over magnesium sulphate and concentrated *in vacuo*. The crude product was then purified by flash chromatography (ethyl acetate:petrol, 1:4 by volume).
Chapter Four

Experimental

**Dimethyl 2-benzylsuccinate (229)**

Dimethyl itaconate (0.21 g, 1.308 mmol) and phenylboronic acid (0.410 g, 3.36 mmol), were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.26 g, 85% yield); \( R_f \) (petrol:ethyl acetate, 9:1) 0.2; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1736 (C=O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 7.2 – 7.1 (5H, m, Ar), 3.60 (3H, s, CH\(_3\)), 3.57 (3H, s, CH\(_3\)), 3.2 - 3.1 (2H, m, CH\(_2\), CH), 2.7 - 2.9 (2H, m, CH\(_2\)), 2.34 (1H, dd, \( J \) 4.8, 16.8 Hz, CH\(_2\)); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 175.0, 172.6, 138.5, 129.4, 128.9, 127.4, 52.3, 52.1, 43.4, 38.1, 35.2; \( m/z \) (FAB+) 237. Due to only a small amount of material available no further data was able to be collected.
4.4 ESTERIFICATION OF A NON-CONJUGATED CARBOXYLIC ACID IN THE PRESENCE OF A CONJUGATED ACID.

**General Procedure**

\[
\text{HO} \quad \text{NiCl}_2 \cdot 6\text{H}_2\text{O (10mol\%)} \quad \text{ROH, reflux} \quad \text{HO} \quad \text{O} \quad \text{O} \quad \text{OH} \quad \text{RO} \]

Itaconic acid (10 mmol), and NiCl$_2$·H$_2$O (2 mmol, 0.2 equiv.) were refluxed in alcohol (10 mL) for 48 hours. The reaction mixture was then cooled to room temperature and diluted with diethyl ether (20 mL). This was then washed with water and saturated sodium bicarbonate solution sequentially (3 x 10 mL). The aqueous extracts were combined and acidified to pH 1 with 1M HCl. The ester was extracted with diethyl ether (3 x 10 mL) and the combined extracts were concentrated _in vacuo_. The product could then be used without further purification.
2-((Methoxycarbonyl)methyl)acrylic acid (241)

Itaconic acid (1.30 g, 10 mmol) and methanol (10 mL) were reacted under the standard protocol to generate the desired compound as colourless crystalline needles (1.12 g, 78% yield); mp (hexane) 67°C; Rf (petrol:ethyl acetate, 4:1) 0.08; νmax (Nujol)/cm⁻¹: 2638 (COOH), 1728 (C=O), 1686 (COOH), 1632 (C=C), 1204 (C-O), 1168 (C-O); δH (300 MHz; CDCl₃) 11.78 (1H, s, OH), 6.41 (1H, s, C=CH), 5.78 (1H, s, C=CH), 3.64 (3H, s, CH₃), 3.28 (2H, s, CH₂); δC (75.5 MHz; CDCl₃) 171.9, 171.4, 133.5, 131.4, 52.6, 37.5; m/z (FAB+) 144 (99%, M⁺+H)[found 144.042908 M⁺+H⁺]; Anal. Calc'd for C₁₇H₁₈O₄; C, 50.00; H, 5.59; N, 0.00. Found: C, 50.5; H, 5.69; N, 0.00.
2-(((Benzyloxy)carbonyl)methyl)acrylic acid (243)

Itaconic acid (1.30 g, 10 mmol) and Benzyl alcohol (10 mL) were reacted under the standard protocol to generate the desired compound as colourless crystalline needles (1.52 g, 69% yield); mp (hexane) 95°C; R\textsubscript{f} (petrol:ethyl acetate, 4:1) 0.12; \( \nu_{\text{max}} \) (Nujol)/cm\textsuperscript{-1} 2725 (OH), 1723 (C=O), 1708 (COOH), 1623(C=C); \( \delta \)\textsubscript{H} (300 MHz; CDCl\textsubscript{3}) 7.4 - 7.3 (5H, m, Ar), 6.59 (1H, s, C=CH), 5.85 (1H, s, C=CH), 5.17 (2H, s, CH\textsubscript{2}), 3.41 (2H, s, CH\textsubscript{2}); \( \delta \)\textsubscript{C} (75.5 MHz; CDCl\textsubscript{3}) 171.3, 170.8, 136.1, 133.5, 131.4, 128.9, 128.7, 128.6, 67.2, 37.7; m/z (FAB+) 221 (99%, M\textsuperscript{+}+H).
4.5 ESTERIFICATION OF CONJUGATED CARBOXYLIC ACIDS

General Procedure

To a solution of 1-(3-di-methylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDCI) (97.7 mg, 0.510 mmol), in dry DCM (10 mL) was added the acid (0.510 mmol) in dry DCM (5 mL), and the solution was stirred at room temperature for 30 minutes. To this mixture was added the alcohol in (0.255 mmol) in dry DMF and 4-(N,N-dimethylamino)pyridine (DMAP) (10 mol%) and the mixture was stirred for a further 20 hours. The reaction was quenched with aqueous ammonium chloride and the product extracted with ethyl acetate (3 x 10 mL). The combined organic extracts were washed with water (2 x 10 mL), brine (2 x 10 mL) and dried over magnesium sulphate. The residue was purified by flash column chromatography, hexane:ethyl acetate (3:1).
**4-Benzyl 1-methyl 2-methylenesuccinate (244)**

![Structure of 4-Benzyl 1-methyl 2-methylenesuccinate](image)

2-(((Benzyloxy)carbonyl)methyl)acrylic acid (0.22 g, 1 mmol) and methanol (10 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.047 g, 20% yield); Rf (petrol:ethyl acetate, 4:1) 0.3; δH (300 MHz; CDCl3) 7.4 - 7.2 (5H, m, Ar), 6.31 (1H, d, 1.2 Hz, C=CH), 5.66 (1H, d, 1.2 Hz, C=CH), 5.13 (2H, s, CH2), 3.57 (3H, s, CH3), 3.28 (2H, d, 1.1 Hz, CH2); δC (75.5 MHz; CDCl3) 171.5, 166.3, 136.17, 134.12, 129.3, 126.9, 128.6, 128.5, 67.2, 52.4, 37.9; Due to only a small amount of material being available no other data was collected.
4.6 ESTERIFICATION OF BOTH THE CONJUGATED ESTER AND NON-CONJUGATED ESTER

General Procedure

\[ \text{Itaconic acid (10 mmol), and NiCl}_2\cdot6\text{H}_2\text{O (2 mmol, 0.2 equiv.) were refluxed in the} \]
\[ \text{alcohol (10mL) for 48 hours. The reaction mixture was then cooled to room} \]
\[ \text{temperature and diluted with diethyl ether (20 mL). This was washed with water and} \]
\[ \text{saturated sodium bicarbonate solution sequentially (3 x 10 mL). The organic extracts} \]
\[ \text{were then reduced in vacuo, and the residue purified by flash column} \]
\[ \text{chromatography (hexane:ethyl acetate, 6/1).} \]
Dibenzyl 2-methylenesuccinate (245)

Itaconic acid (0.130 g, 1 mmol) and benzyl alcohol (10 mL) were reacted under the standard protocol to generate the desired compound as a colourless oil (0.049 g, 16% yield); \( R_f \) (petrol:ethyl acetate, 4:1) 0.2; \( v_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1739 (C=O), 1641 (C=C); \( \delta_H \) (300 MHz; CDCl\(_3\)) 7.36 (10H, s, Ar), 6.42 (1H, s, C=CH), 5.75 (1H, s, C=CH), 5.20 (2H, s, PhCH\(_2\)), 5.13 (2H, s, PhCH\(_2\)), 3.44 (2H, s, CH\(_2\)) \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 170.9, 166.3, 136.1, 134.1, 129.4, 128.9, 128.7, 128.6, 128.5, 67.2, 67.1, 38.2; Anal. Calc’d for C\(_{19}\)H\(_{18}\)O\(_4\); C, 73.53; H, 5.85; N, 0.00. Found: C, 73.3; H, 5.85; N, 0.00.

Bis((1R,2S,5R)-2-isopropyl-5-methylcyclohexyl) 2-methylenesuccinate (246)

Itaconic acid (0.130 g, 1 mmol) and menthol (0.31 g, 2 mmol) in DCM (10 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.041 g, 10% yield); \( R_f \) (petrol:ethyl acetate, 4:1) 0.15; \( v_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1739 (C=O), 1641(C=C), 1140 (C-O), 1081 (C-O); \( \delta_H \) (300 MHz; CDCl\(_3\)) 6.22 (1H, s, C=CH), 5.58 (1H, s, C=CH), 4.6 - 4.5 (2H, m, CH), 3.4 - 3.2 (2H, m, CH\(_2\)), 2.0 - 1.8 (4H, m, CH), 1.8 - 1.6 (4H, m, CH, CH\(_2\)), 1.6 - 1.4 (6H, m, CH\(_2\)), 1.3 - 1.1 (4H, m, CH\(_2\)), 0.9 - 0.8 (18H, m, CH\(_3\)); \( \delta_C \) (75.5 MHz; CDCl\(_3\)) 170.6, 166.0, 134.9, 128.1, 75.2, 75.0, 47.7, 41.1, 38.5, 34.9, 34.7, 34.6, 32.0, 31.8, 31.7, 26.7, 26.6, 26.2, 23.9, 23.8, 22.6, 22.4, 21.4, 21.1, 16.7.
4.7 SYNTHESIS OF POTASSIUM ORGANO TRIFLUOROBORATES FROM ORGANOBORONIC ACIDS

General Procedure

To a concentrated solution of the organoboronic acid (1.2 mmol) in methanol (3 mL) at room temperature, a saturated aqueous solution of potassium difluorohydride (4 mmol, 3.3 equiv) (caution: use Teflon vessel) was added dropwise. A heavy white precipitate was formed. Following the addition, the solvent was removed in vacuo at 40-50°C and the residual solid was thoroughly dried. It was then extracted with acetone (twice at room temperature and once with boiling solvent), the combined extracts were filtered and concentrated in vacuo. The product was used without further purification.
Potassium 1-naphthyltrifluoroborate (264)

1-Naphthylboronic acid (0.206 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as a colourless crystalline solid (0.19 g, 94% yield); mp (acetone) 100°C; Rf (petrol:ethyl acetate, 3:1) 0.11; νmax (Nujol)/cm⁻¹ 1630 (Ar); δH (300 MHz; ((CD3)2CO) 8.5 – 8.4 (1H, m, Ar), 7.6 – 7.5 (2H, m, Ar), 7.5 – 7.4 (1H, m, Ar), 7.2 – 7.1 (3H, m, Ar); δC (75.5 MHz; ((CD3)2CO) 132.1, 126.6, 126.5, 124.9, 124.4; δB(96 MHz; ((CD3)2CO) 4.9; Data identical to those in literature.¹⁰⁵

Potassium 4-acetylphenyltrifluoroborate (265)

4-Acetylphenylboronic acid (0.196 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as a pale yellow solid (0.22 g, 82% yield); mp (acetone) 302°C; Rf (petrol:ethyl acetate, 3:1) 0.06; νmax (Nujol)/cm⁻¹ 1758 (C=O), 1461 (Ar); δH(300 MHz; ((CD3)2CO) 7.72 (2H, d, J 7.7 Hz, Ar), 7.65 (2H, d, J 7.7 Hz, Ar), 2.49 (3H, s, CH3); δC (75.5 MHz; ((CD3)2CO) 196.5, 134.6, 134.4, 133.8, 132.1, 127.3, 119.4, 28.4; δB(100 MHz; ((CD3)2CO) 4.1; Data identical to those in literature.¹⁰⁵
Potassium 4-chlorophenyltrifluoroborate (266)

4-Chlorophenylboronic acid (0.187 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as a colourless solid (0.21 g, 81% yield); mp (acetone) decomposed at 320°C; Rf (petrol:ethyl acetate, 3:1) 0.21; vmax (Nujol)/cm⁻¹ 1588 (Ar), 1458 (Ar), 721 (CCl); δH (300 MHz; ((CD₃)₂CO) 7.45 (2H, d, J 8.0 Hz, Ar), 7.11 (2H, d, J 7.6 Hz, Ar); δC (75.5 MHz; ((CD₃)₂CO) 134.6, 134.5, 131.8, 127.4; δB (100 MHz; ((CD₃)₂CO) 4.4; Data identical to those in literature. ¹⁰⁵

Potassium phenyltrifluoroborate (267)

Phenylboronic acid (0.146 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as colourless flakes (0.19 g, 90% yield); mp (acetone) decomposed at 310°C; Rf (petrol:ethyl acetate, 3:1) 0.08; vmax (Nujol)/cm⁻¹ 1490 (Ar); δH (300 MHz; (CD₃)₂CO) 7.5 – 7.3 (2H, m, Ar), 7.2 – 7.1 (3H, m, Ar); δC (75.5 MHz; (CD₃)₂CO) 132.9, 132.8, 127.4, 126.3; δB (MHz; ((CD₃)₂CO) 4.6; Data identical to those in literature. ¹⁰⁵
Potassium 3-methoxyphenyltrifluoroborate (269)

3-Methoxyphenylboronic acid (0.182 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as a yellow solid (0.21 g, 83% yield); mp (acetone) 294°C; \( R_f \) (petrol:ethyl acetate, 3:1) 0.17; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 2851 (OCH\(_3\)), 1576 (Ar); \( \delta_H \) (300 MHz; \((\text{CD}_3)_2\text{CO}\)) 7.5 - 7.4 (1H, m, Ar), 6.7 - 6.6 (3H, m, Ar), 3.75 (3H, s, CH\(_3\)); \( \delta_C \) (75.5 MHz; \((\text{CD}_3)_2\text{CO}\)) 129.8, 129.7, 128.7, 127.6, 126.8, 114.2, 55.9; \( \delta_B \)(100 MHz; \((\text{CD}_3)_2\text{CO}\)) 4.3; Data identical to those in literature.\(^{120}\)

Potassium 4-methoxyphenyltrifluoroborate (270)

4-Methoxyphenylboronic acid (0.182 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as yellow crystals (0.25 g, 96% yield); mp (acetone) decomposed at 273°C; \( R_f \) (petrol:ethyl acetate, 3:1) 0.2; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 2853 (OCH\(_3\)); \( \delta_H \) (300 MHz; \((\text{CD}_3)_2\text{CO}\)) 7.36 (2H, d, \( J \) 8.3 Hz, Ar), 6.68 (2H, d, \( J \) 8.0 Hz, Ar), 3.70 (3H, s, CH\(_3\)); \( \delta_C \) (75.5 MHz; \((\text{CD}_3)_2\text{CO}\)) 133.8, 133.6, 132.4, 131.9, 119.6, 113.1, 55.4; \( \delta_B \)(100 MHz; \((\text{CD}_3)_2\text{CO}\)) 4.7; Data identical to those in literature.\(^{105}\)
Potassium 4-bromophenyltrifluoroborate (272)

![Structure](image)

4-Bromophenylboronic acid (0.240 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as pale yellow solid (0.27 g, 86% yield); mp (acetone) decomposed at 310°C; R\(_f\) (petrol:ethyl acetate, 3:1) 0.05; \(\nu_{\text{max}}\) (Nujol)/cm\(^{-1}\) 1580 (Ar), 1462 (Ar), 740 (CBr); \(\delta\)\(_H\) (300 MHz; ((CD\(_3\))\(_2\)CO) 7.42 (2H, d, \(J\) 7.8 Hz, Ar), 7.27 (2H, d, \(J\) 8.1 Hz, Ar); \(\delta\)\(_C\) (75.5 MHz; ((CD\(_3\))\(_2\)CO) 135.1, 135.0, 130.6, 120.6; \(\delta\)\(_B\) (100 MHz; ((CD\(_3\))\(_2\)CO) 4.4; Data identical to those in literature.\(^{100}\)

Potassium 3-bromophenyltrifluoroborate (273)

![Structure](image)

3-Bromophenylboronic acid (0.240 g, 1.2 mmol) was reacted under the standard protocol to generate the desired compound as a pale yellow solid (0.26 g, 82% yield); mp (acetone) 173-5°C; R\(_f\) (petrol:ethyl acetate, 3:1) 0.03; \(\nu_{\text{max}}\) (Nujol)/cm\(^{-1}\) 1554 (Ar), 1460 (Ar), 733(C-Br); \(\delta\)\(_H\) (300 MHz; ((CD\(_3\))\(_2\)CO) 7.45 (1H, s, Ar), 7.28 (1H, d, \(J\) 7.1 Hz, Ar), 7.06 (1H, d, \(J\) 7.2 Hz, Ar), 6.91 (1H, t, \(J\) 7.5 Hz, Ar); \(\delta\)\(_C\) (75 MHz; ((CD\(_3\))\(_2\)CO) 135.6, 131.5, 130.9, 129.8, 129.2, 122.6; \(\delta\)\(_B\) (100 MHz; ((CD\(_3\))\(_2\)CO) 4.0; Data identical to those in literature.\(^{100}\)
4.8 RHODIUM CATALYSED ASYMMETRIC ADDITION OF POTASSIUM ORGANO(TRIFLUORO)BORATES TO DIMETHYL ITACONATE.

General Procedure

[Rh(COD)_2][PF_6] (0.004 g, 0.0075 mmol, 3 mol%) and (R)-BINAP (0.009 g, 0.0015 mmol) were added to a pressure tube. Degassed benzene (2 mL) was added after degassing and back filling with argon. After stirring briefly dimethyl itaconate (0.039 g, 0.25 mmol), potassium organotrifluoroborate (0.5 mmol, 2 equiv.) and water (0.1 mL) were added. The resulting solution was stirred at 110°C for 16 hours. The mixture was allowed to cool to room temperature, diluted with water (10 mL) and the product extracted with diethyl ether (3 x 15 mL). The combined extracts were washed with brine (3 x 10 mL), dried over magnesium sulphate and concentrated \textit{in vacuo}. The crude product was then purified by flash chromatography (ethyl acetate:petrol, 1:4 by volume).
**Dimethyl 2-benzylsuccinate (229)**

![Chemical structure](image)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluorophenylborate (0.092 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under standard protocol to generate the desired compound as a pale yellow oil (0.03 g, 51% yield, 68% ee).

Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min⁻¹, \( t_R = 10.6 \) (R) and 12.4 (S).

**Dimethyl 2-((naphthalen-1-yl)methyl)succinate (232)**

![Chemical structure](image)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(1-naphthyl)borate (0.117 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.04 g, 56% yield, 60% ee).

Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min⁻¹, \( t_R = 19.0 \) (R) and 28.9 (S).
Chapter Four

Dimethyl 2-(4-methoxybenzyl)succinate (234)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(4-methoxy-phenyl)borate (0.107 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.064 g, 93% yield, 62% ee).

Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min⁻¹, tR = 11.2 (R) and 16.5 (S).

Dimethyl 2-(4-acetylbenzyl)succinate (237)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(4-acetyl-phenyl)borate (0.113 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.066 g, 96% yield, 48% ee).

Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min⁻¹, tR = 20.9 (R) and 33.4 (S).
Dimethyl 2-(4-chlorobenzyl)succinate (238)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(4-chloro-phenyl)borate (0.109 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow solid (0.067 g, 96% yield, 60% ee).

Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min\(^{-1}\), \(t_R = 7.7\) (R) and 13.7 (S).
Dimethyl 2-(4-bromobenzyl)succinate (278)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(4-bromo-phenyl)borate (0.131 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.077 g, 95% yield, 58% ee); Rf (petrol:ethyl acetate, 9:1) 0.18; v_max (Nujol)/cm⁻¹ 1742 (C=O), 1265 (C-O), 702 (CBr); δ_H (300 MHz; CDCl₃) 7.34 (2H, d, J 8.4 Hz, Ar), 6.96 (2H, d, J 8.4 Hz, Ar), 3.59 (3H, s, OCH₃), 3.58 (3H, s, OCH₃), 3.1 – 3.0 (1H, m, CH), 2.92 (1H, dd, J 6.6, 13.5 Hz, CH₂), 2.67 (1H, dd, J 7.8, 13.5 Hz, CH₂), 2.60 (1H, dd, J 8.7, 16.8 Hz, CH₂), 2.33 (1H, dd, J 5.2, 16.7 Hz, CH₂), δ_C (75.5 MHz; CDCl₃) 174.8, 172.5, 137.6, 132.1, 131.2, 121.1, 52.4, 52.3, 43.2, 37.5, 35.3; m/z (FAB⁺) 315 (20% M⁺+H) [315.024117 found M⁺+H C₁₃H₁₆O₄⁺ seventy nine Br₁ requires M 315.023195; Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min⁻¹, t_R = 8.0 (R) and 14.5 (S).
Dimethyl 2-(3-bromobenzyl)succinate (275)

Dimethyl itaconate (0.039 g, 0.25 mmol), potassium trifluoro(3-bromo-phenyl)borate (0.131 g, 0.5 mmol), benzene (2 mL) and water (0.1 mL) were reacted under the standard protocol to generate the desired compound as a pale yellow oil (0.075 g, 93% yield, 60% ee); R_f (petrol:ethyl acetate, 9:1) 0.2; \( \nu_{\text{max}} \) (Nujol)/cm\(^{-1}\) 1742 (C=O), 1078 (C-O), 730 (CBr); \( \delta_{\text{H}} \) (300 MHz; CDCl\(_3\)) 7.30 (1H, dt, J 1.5, 7.8 Hz, Ar), 7.25 (1H, s, Ar), 7.10 (1H, t, J 7.7 Hz, Ar), 7.02 (1H, d, J 7.5 Hz, Ar), 3.61 (3H, s, OCH\(_3\)), 3.59 (3H, s, OCH\(_3\)), 3.1 – 3.0 (1H, m, CH), 2.94 (1H, dd, J 6.6 Hz, 13.5, CH\(_2\)), 2.68 (1H, dd, J 8.1, 14.1 Hz, CH\(_2\)), 2.62 (1H, dd, J 8.5, 16.8 Hz, CH\(_2\)), 2.34 (1H, dd, J 5.1, 16.8 Hz, CH\(_2\)), \( \delta_{\text{C}} \) (75.5 MHz; CDCl\(_3\)) 174.7, 172.5, 140.1, 132.4, 130.5, 130.3, 128.1, 122.6, 52.5, 52.3, 43.8, 37.7, 35.3; m/z (FAB\(^+\)) 315 (20% \( M^+ + H \)) \( [315.024117 \text{ found} \) \( M^+ + H \) \( C_{13}H_{16}O_4^{+} \) \( \text{requires} \) \( M^+315.023195 \)); Diacel Chiralcel OD-H, hexane/propan-2-ol (95:5), 1.0 mL min\(^{-1}\), \( t_R = 19.0 \) (R) and 28.9 (S).

Rhodium catalysed addition of boronic acids to anhydrides: a new method for the synthesis of ketones

Christopher G. Frost* and Kelly J. Wadsworth

Received (in Cambridge, UK) 22nd August 2001, Accepted 26th September 2001
First published as an Advance Article on the web 24th October 2001

The efficient transmetalation from boron to rhodium is exploited in a new synthesis of aryl and alkenyl ketones.

The rhodium catalysed addition of boronic acids to organic electrophiles has recently emerged as an important tool for organic synthesis. An efficient transmetalation between boron and rhodium permits the addition of organoboronic acids to a range of activated olefins. Significant advances have also been made in the coupling of unactivated olefins in aqueous media. Further to this the addition of aryl boronic acids to aldehydes and imines has been achieved. The mechanism of these transformations is proposed to involve transmetalation between the boronic acid and the rhodium d4 complex to afford an R-RH4 species. The nucleophilic R group then adds to the coordinated electrophile yielding either a Rh bound enolate or alkoxide which is subsequently hydrolysed. As part of our research programme developing catalysis for the functionalisation of aromatics, we were interested in the boron-rhodium transmetalation process as a means to promote the equivalent of a Friedel-Crafts acylation reaction of deactivated arenes. This is a demanding transformation which is not readily achieved by even the most effective Lewis acid catalysts. In this communication we wish to report our development of an efficient rhodium catalysed addition reaction that allows the synthesis of ketones from boronic acids under mild conditions.

To demonstrate this concept, initial experiments examined the reaction of phenylboronic acid (1.6 equiv) 1 with acetic anhydride 2 in the presence of 5 mol% of various rhodium complexes (Scheme 1).6 As summarised in Table 1, the formation of acetophenone 3 is symptomatic of an effective protocol for ketone synthesis.

The first point to note is that in the absence of catalyst no product formation is observed. It was interesting to learn that the Rh(acac) complexes favoured for addition to activated olefins, were not particularly effective in this case (entries 2-7). Similarly, the use of Rh(OAc)2 and RhCl3·3H2O afforded disappointing results (entries 10 and 11). Gratifyingly, the use of [Rh(alkene)Cl]2 complexes showed more promise (entry 9).

*Yield after 2 hours. Yield after 24 hours.
resulting in the formation of 3 in excellent overall yield in the best case (entry 12). The choice of solvent had a clear effect on the efficiency of the reaction (entries 12–16) with the reaction proceeding smoothly in dioxane and 1,2-dimethoxyethane (DME). The insensitivity of this protocol towards air and water (entry 13) is extremely beneficial from a practical perspective. At 65 °C in DME the reaction was complete within two hours, while at room temperature the reaction required 24 hours to afford comparable yields (entries 16 and 17). Furthermore, the catalyst loading could be lowered to 1.5 mol% with the product 3 being obtained in 87% yield after 16 hours. Upon lowering to 0.1 mol% of catalyst, a modest 37% of 3 was isolated after the same period of time.

Under the optimized conditions the reaction was examined with respect to the scope of the boronic acid (Table 2). An attractive feature of this methodology is the commercial availability of a wide range of boronic acids. An important point to note about the presented reaction is the regiospecific formation of product with the electrophile substituting the boronic acid group. Therefore, whilst electronic effects (inductive and resonance) may influence the rates of the reactions, as a consequence of the macroscopic distortions the transmetallation and transfer processes, the composition of product is unaffected by the nature and position of substituent in the starting boronic acid. This offers a significant strategic advantage over Lewis acid catalysed electrophilic substitution processes. Thus, the reaction can be designed to achieve typical electrophilic substitution reactions (Table 2, entry 3). Conversely, the formation of meta- or para-substituted deactivated aromatics can be achieved in excellent isolated yield (Table 2, entries 1, 2 and 4). The results also confirm the scope of the reaction with the alternative electrophilic boronic acids (Table 2, entries 6–10). Furthermore, the reaction can be extended to alternative electrophilic compounds with no significant loss in efficiency. As the present time, difficulties have been encountered in extending the methodology to acid chlorides. Further investigations are directed towards accomplishing this and the addition of organolithiums and to other electrophiles.

In summary, a new rhodium catalysed addition of boronic acids has been developed that allows the synthesis of ketones. This transformation proceeds in good yield for a range of boronic acids. Importantly, this new methodology offers specific advantages over traditional Lewis acid catalysed acylation reactions in that it allows the regiospecific functionalization of activated, unactivated and deactivated aromatics.

Abstract

The enantioselective rhodium-catalysed conjugate addition of aryI boronic acids to dehydroalanine derivatives has been successfully carried out in the presence of \( \text{C}_2\)-symmetric aryl diphosphite ligand (R,R,R)-4 to prepare unnatural amino acid esters. The products have been obtained in up to 72% ee and with good isolated yield.

1. Introduction

The rhodium-catalysed addition of boronic acids to organic electrophiles has emerged as important methodology for organic synthesis. An efficient transmetalation between boron and rhodium permits the addition of organoboronic acids to a range of activated alkenes [1], alkynes [2], aldehydes [3] and anhydrides [4]. The use of the enantiopure diphosphine ligand BINAP (R)-1 enables an enantioselective addition to cyclic enones and activated acyclic \( \beta\)-alkenes [5]. Recent work by Hayashi et al. [6] has elucidated the key steps in the catalytic cycle and revealed that [Rh(OH)(BINAP)] complexes are the most effective pre-catalysts for the enantioselective addition. The reason for the improved activity is in part due to the high oxophilicity of boron resulting in an acceleration in the rate of transmetalation. Previously, a-substituted activated alkenes had not customarily been employed as substrates owing to their low reactivity. However, Hayashi et al. [7] have reported that 1-nitrocyclohexene is a satisfactory substrate in the enantioselective addition affording products with high enantioselectivity and good diastereoselectivity controlled by protonation. In addition to this, work from our group has revealed a rhodium-catalysed conjugate addition of boronic acids to \( \alpha,\beta\)-dehydroalanine derivatives allowing rapid access to a wide range of substituted phenylalanine amino acids [8]. Li and coworkers [9] first reported the analogous addition reaction using organoborane and organobismuth reagents. The corresponding enantioselective reaction has been achieved by Reetz et al. [10] who reported one example of this type of transformation to prepare the naturally occurring amino acid phenylalanine. Importantly, Reetz noted that the BINAP-derived rhodium catalyst afforded excellent activity (100% conversion) but racemic product, whereas less-electron-rich diphosphite ligands such as (R,R)-2 afforded 37% ee increasing to 77% ee when 3,3'-dibromo-1,1'-binaphthyl-2,2'-diol-derived diphosphite ligand (R,R)-3 was used. In this case, enantioselectivity is influenced by facial selectivity and protonation. In this paper, we wish to present our studies on the enantioselective synthesis of amino acids by the addition of aryl boronic acids to \( \alpha,\beta\)-dehydroalanine derivatives catalysed by a rhodium complex of an enantiopure diphosphite (R,R,R)-4. This ligand was first reported by Pringle and coworkers [11] for nickel-catalysed hydrocyanations and has since been used in a variety of catalytic, enantioselective processes (Scheme 1).
2. Results and discussion

The ligands (R,R,R)-4 and (S,S,S)-4 were prepared in good yield by the literature methods [11]. Initial experiments examined the enantioselective addition of 1-naphthalenemethanol to α-phthalimidoacrylic ester (5) [12] and commercially available α-acetamidoacrylic ester (7); selected results are shown in Table 1. Disappointingly, there was no enantioselectivity using substrate 5, although in the case of the (R)-1-derived rhodium complex (entry 1), isolated yields of product 6 were excellent. To investigate whether the observed low enantioselectivity is a direct result of product racemisation under the reaction conditions, a sample of (S)-1-(N-phthalalimidophenyl)alanine ethyl ester (8b) was subjected to the reaction conditions. Analysis of the recovered amino acid derivative showed no change in enantioselectivity to that of the starting substrate (Scheme 2).

Scheme 1. Ligands for rhodium-catalysed addition of boronic acids.

Scheme 2. Results and discussion.
Better results in terms of enantioselectivity (up to 72% ee) were obtained when 7 was used as substrate (entries 5-9). It was noteworthy that the rhodium source had a significant influence on enantioselectivity. Pertinent to this is the reactivity of the rhodium source in the absence of ligand (entries 11-14). The highest enantioselectivities result from the use of \([\text{Rh(acac)}(\text{C}_2\text{H}_4)_2]\) and \([\text{Rh(COD)}\text{Cl}]_2\), both of which are ineffective without added ligand. NMR experiments indicate that ligand exchange ([R,R,R]-4/(C_2H_4),) is complete within 10 min at 25 °C, whereas exchange of COD is slower. The significant catalytic activity of \([\text{Rh(COD)}\text{Cl}]_2\) and \([\text{Rh(OH)}(\text{COD})]_2\) results in an increased proportion of racemic product thus lowering the overall enantioselectivity. The enantioselectivities obtained under optimised conditions were repeatable and as would be expected, the use of the opposite enantiomer of ligand (S,S,S)-4 afforded a reversal in the sense of asymmetric induction (entry 6).

From the preceding results, the favoured pre-catalyst/ligand combination was revealed as \([\text{Rh(acac)}(\text{C}_2\text{H}_4)_2]/(\text{R,R,R})-4\). Using the preferred conditions the scope of the process was explored with respect to the boronic acid (Table 2). In all cases, the reaction proceeded in good yield with moderate but significant enantioselectivities. It was useful to note that both electron-rich and electron-deficient aryl boronic acids could be successfully employed using diphosphite ligand (R,R,R)-4. This

*General conditions: Rh (3 mol%), ligand (3.3 mol%), enamide (0.5 mmol), boronic acid (2 mmol), NaF (1.5 mmol), dioxane (1.5 ml), H_2O (150 µl), 100 °C, 24 h. Isolated yield after flash chromatography/Determined by HPLC analysis using a chiral column (Chiralpak AD (10% 2-PrOH/Hexane)).
is in contrast to [Rh(acac)(HCH)] which is known to affect the hydrolysis of electron-rich α,β-unsaturated acids at 100 °C [6].

3. Conclusion

In summary, the use of enantiomerically pure diphosphite ligands has enabled the scope of the rhodium-catalysed addition of boronic acids to dehydroalanine derivatives. The prospect of tuning the ligand backbone to increase the facial selectivity of the dehydroalanine derivatives is currently being explored.

4. Experimental

Reactions were performed under a dry nitrogen atmosphere. Anhydrous dioxane was purchased from Sigma Aldrich and used as purchased, water was deoxygenated by sparging with nitrogen for 30 min and all other reagents were used without further purification. Melting points were determined using a Buchi 535 melting point apparatus and are uncorrected. Infrared spectra (4000 - 600 cm⁻¹) were recorded on a Perkin Elmer FT 1000 spectrometer with internal SiMe₄ standard for L H- and 13C NMR.

4.1. A typical procedure for the rhodium-catalysed 1,4 addition of boronic acids to dehydroalanine derivatives

An oven-dried Schlenk tube under nitrogen is charged with [Rh(acac)(HCH)] (3.9 mg, 15 pmol), ligand (16 μmol), NaF (63 mg, 1.5 mmol) and dioxane (1.5 ml). The mixture was stirred under an atmosphere of nitrogen at 100 °C for 24 h. After cooling to r.t. the solution was dissolved in ethyl acetate (3 ml) and water (5 ml) added. The aqueous layer was separated and extracted with ethyl acetate (3 x 5 ml), the combined organics were washed with brine (10 ml), dried (MgSO₄) and concentrated in vacuo. The residue was purified by silica gel column chromatography.

The rhodium catalysed addition of potassium trifluoromethylborates to dimethyl itaconate generates an iminium complex which on protonation provides enantiomerically enriched succinic esters.

The rhodium catalysed asymmetric addition of allyl and alkanyl organoboranes to activated alkenes has emerged as fundamental methodology for organic synthesis. The reaction can be carried out in aqueous solvent and affords excellent enantioselectivities (>90% ee) across a wide range of substrates. Interestingly, there are limited reports of substituted activated alkenes being employed as substrates. This can be attributed to the lower reactivity and reactivity, or in the asymmetric process the enantioselectivity is determined at the hydrolysis step of an enantiomERICALLY enriched iminium and not at the insertion step (Fig. 1).1 2

In previous reports, we and others have revealed enantioselective rhodium catalysed additions of organoboranes to alicyclic substrates.4-6 In this paper we wish to present preliminary results in the first enantioselective synthesis of 2-substituted succinic esters by a tandem rhodium carbamoyl conjugate addition-enantioselective protonation.7

A preliminary investigation into the tandem 1,4-addition-enantioselective protonation by the addition of naphthyl or phenylboronic acid to dimethyl itaconate (1) in the presence of Rh(cod)Cl(PF3)2 and (R)-BINAP in water (Fig. 1) failed to afford any product. In an attempt to improve this process by changing or increasing the amount of ligand or solvent, a series of substrates differing in facial or steric hindrance was tested (Scheme 1). It is feasible that diastereomERICally enriched iminium salts, which are easily prepared from the corresponding enantiomer, allow practical advantages in terms of reactivity and stability for rhodium catalysed conjugate addition reactions.2 Our initial experiments confirmed that the addition of 2a to 1 was promoted by complexation from aqueous rhodium salts, with complexes formed from neutral species such as Rh(cod)Cl(PF3)2.

For convenience we performed the addition of trifluoromethylborate salts to dimethyl itaconate (1) in the presence of a stoichiometric Rh(cod)Cl(PF3)2 at room temperature or at 100°C.2a

Rhodium catalysed tandem conjugate addition-protonation: an enantioselective synthesis of 2-substituted succinic esters

dependent on a face selective protonation of the intermediate meta-stable/molecular species. To this purpose, the application of optically-resolved phosphonates as alternative proton sources revealed a significant correlation between structure and enantioselectivity.1,2 However, the system could not be optimized to retain the reproducible selectivity obtained using water.

The practical utility of the methodology was demonstrated by the addition of a diverse range of trifluoromethylboronic acids (2b–j) (Table 1). With the exception of ortho-substituted 2c, the products were isolated at excellent yield and reproducible enantiomeric selectivity. In the presence of (R)-BINAP, the product with (R) configuration was obtained, consistent with the two diastereomeric oxo-allylrhodium intermediate. Of particular note is the alkylation process (addition of 2b and 2j) which provides products that could not ordinarily be obtained by approaches involving enantioselective hydrogenation.

Finally, it should be pointed out that high-temperature (>100 °C) is essential for enantioselectivity. Attempts to lower the reaction temperature resulted in racemic mixtures of product 3a. 12 The multifarious factors that control asymmetric induction in the addition to α-substituted activated alkenes are the subject of continued study and will be reported in due course.

The authors would like to thank Johnson-Matthey for the generous loan of transition-metal salts and Professor Richard Jackson (University of Sheffield) for discussion and insightful comments related to the presented work.

Abstract: The rhodium-catalysed addition of boronic acids to \( \alpha\)-substituted activated alkenes proceeds smoothly in water resulting in a unique synthesis of both succinic esters and \( \beta\)-amino acid derivatives.

Key words: conjugate addition, rhodium, boronic acids, succinic esters, \( \beta\)-amino acids.

Since the first report by Hayashi and Miyaura in 1998, the rhodium-catalysed addition of aryl and alkenyl organometallic reagents to activated alkenes has emerged as important methodology for organic synthesis. Although both Miyaura and Lautens have reported additions to both activated alkenes and heteroaromatic alkenes that proceed with water as solvent, in the majority of reported examples organic solvents are used either alone or as co-solvents. In a previous study we have revealed an efficient rhodium-catalysed conjugate addition of boronic acids to \( \alpha,\beta\)-dehydroamino acid derivatives using water as the only solvent. In an ongoing programme of research we have sought to broaden the scope of this methodology to other \( \alpha\)-substituted activated alkenes. In this paper, we wish to present preliminary results in the synthesis of 2-substituted succinic esters and \( \beta\)-amino acid derivatives. The products from this process are of significant utility as peptidomimetics in the development of pharmaceutical and agrochemical intermediates. The methodology described herein represents a unique alternative to the two-step condensation-hydrogenation approach conventionally employed.

At the outset of this study we chose to investigate the coupling of arylboronic acid (2b) with dimethyl itaconate (1) using water as the reaction solvent. During preliminary optimisation, the catalyst [Rh(cod)Cl]₂ (cod = cycloocta-1,5-diene) was used with sodium dodecylsulfate (SDS) as a phase transfer agent affording a 55% yield of product 3b. In the absence of SDS the yield fell to less than 10%. The addition of two equivalents of sodium carbonate increased the yield to 81%. Under these optimised conditions a number of substituted aryl and vinylboronic acids (2a–i) was tested and, pleasingly, the reaction proceeded in good isolated yields to provide a useful synthetic approach to 2-substituted succinic esters.

![Scheme 1](image-url)

Given the importance of \( \beta\)-amino acids and their derivatives the development of new synthetic methodology to prepare such compounds is of significant interest. We were therefore driven to extend the described methodology to include the addition of aromatic boronic acids to \( \beta\)-amino acids affording \( \beta\)-amino acid derivatives. The orthogonally protected \( \beta\)-aminoacrylate substrate 4 can be prepared in good yield by the reaction of potassium phthalimide (KNPht) with either of bromomethylacrylate or acetoxymethylacrylate. We were pleased to discover that this was a viable route for the synthesis of functionalised \( \beta\)-phenylalanine derivatives. As previously the combination of [Rh(cod)Cl]₂ and sodium dodecylsulfate (SDS) provided a catalyst system for the addition of a range of substituted boronic acids in water (Scheme 2).

The lower reactivity of 4 is evident from the higher...
catalyst loading (10 mol%) and higher temperature (100 °C) necessary to afford acceptable isolated yields of product (13-77%). Nevertheless, this represents a new practical method for the synthesis of highly functionalized \( \beta \)-amino acid derivatives and we are continuing to expand the scope of the transformation. The protecting groups can be cleaved by a two-step route consisting of hydrogenolysis of the phenyl group followed by removal of the phthalyl group with hydrazine. Alternatively, the simultaneous cleavage of both protecting groups can occur under acidic conditions (6 N HCl-HOAc 4:1) affording the \( \beta \)-amino acid hydrochloride salts.3-10

Typical Experimental Procedure

As shown in Scheme 2, racemic 2-substituted succinic esters and \( \beta \)-amino acid derivatives were obtained from the corresponding benzyl protected \( \beta \)-amino acid hydrochloride.4-10

Scheme 2

The key steps in the catalytic cycle have been elucidated and reported by Hayashi. Assuming the mechanistic observations extend to the presented work, it is likely a rhodium-hydride species is the reactive catalyst and the reaction occurs by ary transfer to rhodium followed by coordination of the substrate (4-5) and insertion to generate an \( \pi \)-allyl rhodium species which is hydrolyzed to sodium-hydroxide species is the reactive catalyst and the final product (3/5).

performed at 100°C where a reduction of yield between 6 hours and 24 hours is observed (Graph 1).

Catalyst Loading Study

The study of the optimal catalyst loading proved once again that there is a fine balance in this reaction between the acceleration of the desired reaction and the production of unwanted side products. Although none of these side products were isolated they are likely to include benzene through hydrolysis of the boronic acid.

It is pleasing to note that a 33% yield can be achieved with catalyst loadings of as low as 0.1mol%. However, there is a decrease of 15% yield when the loading is increased from 3mol% to 5mol%. Thus, 3mol% is the optimum catalyst loading for a 16 hour reaction at 65 °C (Table 6).
3 RHODIUM-CATALYSED ADDITIONS TO ITACONATE ESTERS

3.1 AIMS AND OBJECTIVES

The object of this project was to explore the 1,4-addition of organoboronic acids to dialkyl itaconate esters, the products of which are synthetically useful as they are important intermediates for the synthesis of many natural products; for example, matrix metalloproteinase inhibitor 199.

![Figure 1](image)

Figure 1

Initial studies will focus on the racemic synthesis of 2-substituted succinic esters, through the study of a range of rhodium complexes and conditions. It was felt that aqueous conditions would be optimum for environmental reasons as well as suitability towards a range of functional groups. Once optimal conditions have been established, a series of 2-substituted succinic esters will be prepared from a range of boronic acids and a select group of dialkyl itaconate esters.

Once a route to racemic products has been identified, focus will be switched to developing an asymmetric version of this reaction. This will entail an investigation of key reaction parameters including a variety of rhodium salts, enantiopure ligands, organoboranes and additives. After a thorough optimisation a range of 2-substituted succinic esters will be prepared in both (R)- and (S)-configurations.
3.2 BACKGROUND

The synthetic usefulness of 2-substituted succinic esters can be demonstrated by looking at the synthesis of three major drugs, MMP inhibitors, lignan lactones and CNS drugs.

Matrix metalloproteinases (MMP’s) are a group of enzymes involved in the repair, degradation, and remodelling of extracellular matrix proteins in tissues. Since they have a destructive potential, failure to regulate MMP activity in physiological processes may lead to such problems as tissue destruction, and diabetic ulcers. 82 UK-370, 106, 201, a potent and selective MMP-3 inhibitor discovered by chemists at Pfizer, 83 has been developed as a candidate to treat pathological conditions, involving tissue destruction.
Chapter Three  Rhodium-Catalysed Additions To Itaconate Esters

Lignan lactones such as deoxypodophyllotoxin 217 are known to show cytotoxic activities and can be utilised as anti-cancer drugs. Achiwa et al.\textsuperscript{87} synthesised a range of these compounds using the asymmetric form of the above route. A retrosynthesis of which is shown in Scheme 81.

\begin{center}
\includegraphics[width=\textwidth]{scheme81}
\end{center}

\textbf{Scheme 81}

Stobbe condensation of dimethyl itaconate and the required substituted benzaldehyde was followed by asymmetric hydrogenation of the alkene (Scheme 82). The asymmetric hydrogenation was carried out in methanol at 30°C for 40 hours under 1 atm. of H\textsubscript{2} in the presence of triethylamine using the neutral rhodium complex of (4S,5S)-MOD-DIOP 220. This is prepared by mixing [Rh(COD)Cl]\textsubscript{2} and MOD-DIOP in methanol. All reactions gave high optical purity (>93%ee) and quantitative yields. Optically pure (R)-arylmethylsuccinic acid monomethyl esters 219 were easily obtained by a single recrystallisation of the products from isopropyl ether.
mechanism demonstrates how the ligand determines which face the alkene coordinates (Scheme 100).

BINAP has been extensively studied and so the skewed structure of 279 is known to reflect its interaction with transition metals. It can be seen that (S)-BINAP rhodium intermediate 279 has a free space in the lower part of the coordination site. The upper part being blocked by one of the phenyl rings of the BINAP ligand. This forces the alkene of cyclohexenone to coordinate through its \( \alpha \)-si face rather than its \( \alpha \)-re face. Migratory insertion then creates a stereocentre in 280 with absolute configuration (S). This model can be used to predict a host of 1,4-addition products configuration with the (S)-BINAP rhodium intermediate always attacking the \( \alpha \)-si face of the \( \alpha,\beta \)-unsaturated carbonyl.

The situation is complicated further when the protonolysis occurs to form a new chiral centre. For example Hayashi reported that organoboronic acids react with \( \alpha \)-
