Statistical Inference for Multidimensional Inequality Indices

Ramses H. Abul Naga *

August 29, 2008

Abstract

We use the delta method to derive the large sample distribution of multidimensional inequality indices. We also present a simple method for computing standard errors and obtain explicit formulas in the context of two families of indices.

Keywords: multidimensional inequality indices, large sample distributions, standard errors.

JEL codes: D63, C43

*Department of Economics and International Development (University of Bath). I am grateful to the Swiss National Science Foundation for financial support under grant number 100012-108208. I also wish to thank Pierre-Yves Geoffard for discussions. I am solely responsible for any errors or omissions.
Ever since the work of Kolm (1977), there has been a growing theoretical literature on the measurement of multidimensional inequality (e.g. Tsui 1995, 1999; Abul Naga and Geoffard 2006, Gadjos and Weymark, 2006). Empirical work in the area (for instance Justino et al. 2004) is however considerably more scarce. One reason perhaps is that simple methods for undertaking basic inference in relation to multidimensional inequality indices are lacking\(^1\). In this paper therefore we build on the results of Cowell (1999) obtained in the single attribute context, in order to derive the large sample distribution of multidimensional inequality indices. We also present a simple method for computing standard errors and obtain explicit formulas in the context of two families of indices.

1. Framework

Consider data on \(p\) attributes of well-being in relation to a sample of \(n\) individuals. Individual \(i\) has resources \(x_i = (x_{i1}, ..., x_{ip})\), where \(x_i \in \mathbb{R}^p_+\). The joint distribution is a matrix \(X = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \in M^n\), the set of all \(n \times p\) matrices with strictly positive elements. We also let \(\bar{x} = (\bar{x}_1, ..., \bar{x}_p)\) denote the vector of sample means.

A \(p\)-dimensional inequality index is a real valued function \(\hat{I}(X) : M^n \rightarrow \mathbb{R}_+\). A difficulty in developing inference for inequality indices noted previously in the unidimensional context (Cowell, 1999) is that the inequality index will rarely present itself in the form of a linear in \(X\) function.

For example, the multivariate generalization of the class of Atkinson-Kolm-Sen [AKS] indices proposed by Tsui (1995) takes the following form in the context of two attributes:

\[
I^{AKS}(X) = 1 - \left( \frac{1}{n \bar{x}_1^\alpha \bar{x}_2^\beta} \sum_{i=1}^n x_{i1}^\alpha x_{i2}^\beta \right)^{\frac{1}{\alpha + \beta}}
\]  

(1.1)

where \(\alpha\) and \(\beta\) are parameter values chosen by the data analyst in order for the index to satisfy certain ethical properties \(^2\). From the statistician’s perspective

\(^1\) An important exception is Anderson (2004) which derives tests of inequality dominance in a multidimensional context.

\(^2\) For instance, for the index \(I(\cdot)\) to satisfy a property of aversion to correlation increasing transformations of \(X\), \(\alpha\) and \(\beta\) must be chosen to be strictly negative real numbers.
the inequality index is a transformation of three sample moments of \( X \), namely, \( \bar{x}_1, \bar{x}_2 \) and \( s = \frac{1}{n} \sum_{i=1}^{n} x_{i1} x_{i2} \).

More generally, in the context of \( p \) attributes \( \bar{x} \) is a vector of \( p \) sample means, and we can let \( s \) be a \( 1 \times l \) vector of functions:

\[
\frac{1}{n} \sum_{i=1}^{n} g_1(x_{i1}, \ldots, x_{ip}) \quad \cdots \quad \frac{1}{n} \sum_{i=1}^{n} g_l(x_{i1}, \ldots, x_{ip})
\]

Let \( k = p + l \) denote the dimension of the vector of moments \( w = [\bar{x} \ s] \). We can now express a \( p \)-dimensional inequality index \( \hat{I}(X) \) as a function \( F(\bar{x}, s) \), where \( F: \mathbb{R}_+^k \rightarrow \mathbb{R}_+ \).

2. Large sample distribution

We know from the Analogy Principle that under random sampling the inequality index calculated in the data \( \hat{I}(X) \) will result in a consistent estimator of the level of inequality underlying a given population.

Define \( \sigma \) as the population counterpart to \( s \):

\[
\sigma = \begin{bmatrix}
E[g_1(x_i)] & \cdots & E[g_l(x_i)]
\end{bmatrix}
\]

Let \( \mu = (\mu_1, \ldots, \mu_p) \) denote the vector of population means and let \( \omega = [\mu \ \sigma] \). We also let \( \text{cov}(y) \) denote the covariance matrix of a random vector \( y \). Finally, we define the \( 1 \times k \) Jacobian vector \( J \) as follows

\[
J = \frac{\partial F}{\partial \omega} = \begin{bmatrix}
\partial F/\partial \mu & \partial F/\partial \sigma
\end{bmatrix}
\]

In deriving our main result, we shall make the following assumptions:

[A1] The observations \( x_1, \ldots, x_n \) are independently and identically distributed with mean vector \( \mu_o \) and cross-moment vector \( \sigma_o \) where \( \mu_o \) and \( \sigma_o \) are finite \( p \)-dimensional and \( l \)-dimensional vectors.

[A2] \( \text{cov}(n^{1/2}w) = V_o \), where \( V_o \) is a finite \( k \times k \) positive semi-definite matrix.

[A3] The function \( F(\mu, \sigma) \) does not involve \( n \) and is continuously differentiable at the point \( \omega_o = [\mu_o \ \sigma_o] \).

Our purpose here is to obtain the large sample distribution of \( \hat{I}(X) = F(\bar{x}, s) \) as a function of \( I_o = F(\mu_o, \sigma_o) \). For this purpose, we shall use the delta method (Goldberger, 1991, chapter 9).
Proposition 1 Under Assumptions [A1-A3], \( \hat{I}(X) = F(\bar{x}, s) \) converges in distribution to a normal variate:

\[
n^{1/2}[F(\bar{x}, s) - F(\mu_o, \sigma_o)] \longrightarrow N(0, J_oV_oJ_o')
\]

(2.2)

where \( J_o \) is the Jacobian vector given by

\[
J_o = \left. \frac{\partial F}{\partial \omega} \right|_{\omega = \omega_o}
\]

Proof From [A1], the law of large numbers implies that \( \text{plim}(\bar{x}) = \mu_o \) and \( \text{plim}(s) = \sigma_o \). In turn, in relation to [A2] the central limit theorem entails that \( n^{1/2}[\omega - \omega_o] \longrightarrow N(0, V_o) \). Hence, using [A3] the delta method entails that \( n^{1/2}[\hat{I}(X) - I_o] = n^{1/2}[F(\bar{x}, s) - F(\mu_o, \sigma_o)] \) converges to a normal distribution with mean zero and variance \( J_oV_oJ_o' \) where \( J_o = J(\omega_o) \). \( \square \)

3. Standard errors

Let \( \hat{V} \) be any consistent estimator of \( V_o \) and let \( \hat{J} = J(\bar{x}, s) \). In the light of (2.2), we can then obtain an asymptotic standard error for \( \hat{I}(X) \) as

\[
\text{s.e.} \left[ \hat{I}(X) \right] = \left( \hat{J}V\hat{J}' \right)^{1/2}
\]

If we define \( \bar{g}_j \) as the \( j \)th component of \( s \), i.e. \( \bar{g}_j = \sum_{i=1}^{n} g_j(x_i)/n \) and we construct the \( n \times k \) matrix

\[
Z = \begin{bmatrix}
  x_{11} - \bar{x}_1 & \cdots & x_{1p} - \bar{x}_p & g_1(x_1) - \bar{g}_1 & \cdots & g_1(x_n) - \bar{g}_1 \\
  \vdots & & \vdots & \vdots & & \vdots \\
  x_{n1} - \bar{x}_1 & \cdots & x_{np} - \bar{x}_p & g_1(x_n) - \bar{g}_1 & \cdots & g_1(x_n) - \bar{g}_1
\end{bmatrix}
\]

(3.1)

then this asymptotic standard error may be computed as follows:

\[
\text{s.e.} \left[ \hat{I}(X) \right] = \left( \frac{1}{n} \hat{J}Z'Z\hat{J}' \right)^{1/2}
\]

(3.2)

where, in this context, \( \hat{V} = Z'Z/n \). The formula for \( \hat{V} \) is fairly general. However, the form of the Jacobian vector \( \hat{J} \) will vary depending on the structure of the inequality index.
3.1. Indices based on the Cobb-Douglas form

We now return to the simple context of two attributes and consider first inequality indices of the form

\[ \hat{I}(X) = F \left( \frac{1}{n \bar{x}_1 \bar{x}_2} \sum_{i=1}^{n} x_{i1}^{\alpha} x_{i2}^{\beta} \right) \]  
\[ (3.3) \]

The index (1.1) proposed by Tsui (1995) is one such function with \( F(t) = 1 - t^{1/(\alpha+\beta)} \). The multidimensional generalized entropy index (Tsui, 1999) also has the form (3.3) with \( F(t) = \eta t \), for some scalar \( \eta \). As a corollary to Proposition 1, we derive the form of the Jacobian vector in the context of (3.3).

**Corollary 2** For inequality indices in the class (3.3), the Jacobian vector takes the form

\[ \hat{J} = F'(t) \cdot \begin{bmatrix} -\alpha t/\bar{x}_1 & -\beta t/\bar{x}_2 & 1/\bar{x}_1 \bar{x}_2 \end{bmatrix} \]  
\[ (3.4) \]

where \( t = \frac{1}{n \bar{x}_1 \bar{x}_2} \sum_{i=1}^{n} x_{i1}^{\alpha} x_{i2}^{\beta} \).

In the context of (1.1) for instance, the standard error of the inequality index may readily be estimated using the formula (3.2) with:

\[ F'(t) = -\frac{1}{\alpha + \beta} t^{1/(\alpha+\beta)-1} \]  
\[ (3.5) \]

\[ Z = \begin{bmatrix} x_{11} - \bar{x}_1 & x_{12} - \bar{x}_2 & x_{11} \bar{x}_{12} - \frac{1}{n} \sum_{i=1}^{n} x_{i1}^{\alpha} x_{i2}^{\beta} \\
\vdots & \vdots & \vdots \\
x_{n1} - \bar{x}_1 & x_{n2} - \bar{x}_2 & x_{n1} \bar{x}_{n2} - \frac{1}{n} \sum_{i=1}^{n} x_{i1}^{\alpha} x_{i2}^{\beta} \end{bmatrix} \]  
\[ (3.6) \]

In the context of the Tsui (1999) index, the standard error formula is as above with the only difference that \( F' = \eta \) replaces (3.5) as the index is linear in \( t \).

3.2. Indices which are correlation neutral

Indices which are entirely characterized by the marginal distributions of the two attributes are by definition neutral with respect to correlation increasing transformations of the joint distribution \( X \). Such indices are of the form

\[ \hat{I}(X) = F \left( \frac{1}{n} \sum_{i=1}^{n} \phi_1(x_{i1}), \frac{1}{n} \sum_{i=1}^{n} \phi_2(x_{i2}), \phi_1(\bar{x}_1), \phi_2(\bar{x}_2) \right) \]  
\[ (3.7) \]

---

\( ^{3} \)The generalization to \( p > 2 \) attributes is straightforward given our earlier discussion.
Members of this important class include the bivariate generalization of the Gini index (Gadjos and Weymark, 2006) as well as the bivariate mean logarithmic deviation:

\[
\hat{\text{J}}^{\text{MLD}}(X) = 1 - \exp \left( \frac{\delta}{n} \sum_{i=1}^{n} \log (x_{i1}) + \frac{1 - \delta}{n} \sum_{i=1}^{n} \log (x_{i2}) - \delta \log (\bar{x}_1) - (1 - \delta) \log (\bar{x}_2) \right)
\]  

(3.8)

with \(0 < \delta < 1\). There are two moments here other than the two sample means, so we can define \(s_1 = \sum_{i=1}^{n} \log (x_{i1}) / n\) and \(s_2 = \sum_{i=1}^{n} \log (x_{i2}) / n\).

We can readily obtain the asymptotic standard error of the inequality index as follows:

**Corollary 3** For the bivariate mean logarithmic deviation measure (3.8), the Jacobian vector takes the form

\[
\hat{\text{J}} = -\exp(t) \cdot \begin{bmatrix} -\delta/\bar{x}_1 & -(1 - \delta)/\bar{x}_2 & \delta & (1 - \delta) \end{bmatrix}
\]  

(3.9)

where

\[
t = \frac{\delta}{n} \sum_{i=1}^{n} \log (x_{i1}) + \frac{1 - \delta}{n} \sum_{i=1}^{n} \log (x_{i2}) - \delta \log (\bar{x}_1) - (1 - \delta) \log (\bar{x}_2)
\]  

(3.10)

The standard error of the inequality index may readily be estimated using the formula (3.2) with:

\[
Z = \begin{bmatrix}
x_{11} - \bar{x}_1 & x_{12} - \bar{x}_2 & \log(x_{11}) - \frac{1}{n} \sum_{i=1}^{n} \log(x_{i1}) & \log(x_{12}) - \frac{1}{n} \sum_{i=1}^{n} \log(x_{i2}) \\
\vdots & \vdots & \vdots & \vdots \\
x_{n1} - \bar{x}_1 & x_{n2} - \bar{x}_2 & \log(x_{n1}) - \frac{1}{n} \sum_{i=1}^{n} \log(x_{i1}) & \log(x_{n2}) - \frac{1}{n} \sum_{i=1}^{n} \log(x_{i2})
\end{bmatrix}
\]  

(3.11)
