

## 1 **Day One Sustainability**

2 Emissions reductions targets for the UK set out in the Climate Change Act for the peri-  
3 od to 2050 will only be achieved with significant changes to the built environment,  
4 which is currently estimated to account for 50% of the UK's carbon emissions.

5 The socio-technological nature of Civil Engineering means that this field is  
6 uniquely placed to lead the UK through such adaptations. This paper discusses the im-  
7 portance of interdisciplinary teaching to produce multi-faceted team approaches to sus-  
8 tainable design solutions.

9 Methods for measuring success in education are often not fit for purpose, pro-  
10 ducing good students but poor engineers. Real-world failures to apply sustainable de-  
11 sign presents a serious, difficult to detect, and ultimately economically negative situa-  
12 tion. Techniques to replace summative examinations are presented and discussed, with  
13 the aim of enhancing core technical skills alongside those required for sustainable de-  
14 sign.

15 Finally, the role of our future engineers in policy-making is discussed. In addi-  
16 tion to carbon, the provision of water and food will heavily influence the work of civil  
17 engineers in the coming decades. Leadership from civil engineers with the technical  
18 knowledge and social awareness to tackle these issues will be required. This provides  
19 both opportunities and challenges for engineering education in the UK.

20

## 21 **Introduction**

22 The built environment has a huge impact on the environmental, economic and social  
23 well being of the UK. Research has consistently shown that the between 40 and 60% of  
24 UK carbon emissions are associated with activities in the built environment (BIS 2010)  
25 with the majority of this (Morrell 2010; King 2010) coming from energy use in build-  
26 ings.

27 This paper discusses engineering sustainability from the perspective of teaching  
28 and research undertaken at the University of Bath Department of Architecture and Civil  
29 Engineering. A blended delivery of building physics, architecture and civil engineering  
30 is demonstrated as a key way in which academia can work with industry to provide  
31 graduates who have the skills required to meet global challenges beyond 2050.

32 The importance of instilling sustainability in all teaching from day one is pre-  
33 sented and the role of industry, research, material use, and policy are all discussed.  
34 Challenges beyond embodied carbon reduction are introduced in the context of future  
35 teaching, and the role of assessment in all of these aspects is considered before conclu-  
36 sions are drawn.

## 37 ***The University of Bath***

38 The joint Department of Architecture and Civil Engineering at the University of Bath  
39 was formed in 1965, and was led from 1976 by Professor Sir Ted Happold. Its success-  
40 ful approach to teaching engineers and architects together has gathered excellent rank-  
41 ings and student satisfaction in both disciplines.

42 The Department has an annual intake of approximately 200 undergraduate, 60  
43 post-graduate taught and 20 post-graduate research students. The five undergraduate  
44 degree programs (BSc (Hons) Architecture; Master of Architecture; BEng Civil Engi-

45 neering; MEng Civil Engineering; MEng Civil and Architectural Engineering) all offer  
46 placement opportunities.

47 Interdisciplinary research within the Department is currently focused in three  
48 main research groups, the output of each feeding directly into the relevant taught units:

49 (1) The BRE Centre for Innovative Construction Materials (BRE CICM) has 20 re-  
50 search active staff working in innovative and sustainable construction materials  
51 and technologies.

52 (2) The Centre for Advanced Studies in Architecture (CASA) supports collaborative  
53 research amongst architectural history, contemporary design, archaeology, con-  
54 servation, and emerging digital technologies.

55 (3) The Energy and the Design of Environments (EDEn) group research lies primar-  
56 ily in the field of sustainable building design and building physics.

## 57 **Drivers**

58 The Climate Change Act (DECC 2008) sets out binding and ambitious targets for em-  
59 bodied CO<sub>2</sub> emissions reductions (Figure 1). Meeting these targets will require concert-  
60 ed action from many disciplines, with the construction industry being one of the largest  
61 potential contributors to future success (Morrell 2010). Given that there are fewer than  
62 forty years until the target for an 80% reduction in carbon emissions must be met,  
63 providing graduates with the leadership and technical skills required to meet this chal-  
64 lenge is essential.

## 65 **Day one**

66 Giving students both an understanding of the challenges the built environment faces,  
67 and tools to measure their impact upon it, is a critical stage in generating a mindset of

68 sustainability. It is crucial that this is encouraged immediately, and new students on all  
69 degree programmes are introduced to sustainability on day one of their induction  
70 through the ‘Carbon Counter’ pocketbook (Lynas 2007).

71           Since we measure what we care about, and that we adjust our behaviour based  
72 on the metrics we are measured against (Ariely 2010), the ‘carbon counter’ is an appro-  
73 priate first step. The University of Bath also publishes the Inventory of Carbon and En-  
74 ergy (Hammond and Jones 2011), a gold standard in measuring carbon, that is used  
75 throughout studio project work.

76           Providing students with a means by which carbon can be measured, however  
77 approximately, enables them to immediately optimise their approach to sustainability  
78 and has the potential to impact the way they undertake their personal and professional  
79 lives.

## 80 *Year 1*

81 After induction, the first year of education is crucial. ‘Teaching’ sustainability in the last  
82 semester of final year would be of no practical use, as students would not have had  
83 three-years worth of practical experience of making mistakes before they graduate.  
84 Such a late introduction could also give the impression 1) that sustainability is not im-  
85 portant or 2) that it can be bolted on to a project at the end; neither outcome is particu-  
86 larly helpful in conveying the importance of the subject.

87           Taught units with assessment directly relevant to sustainability in the under-  
88 graduate engineering programs within the Department are summarised in Figure 2, with  
89 the unit weighting given to first year clearly evident. Note that credit ratings are under  
90 the European Credit Transfer and Accumulation System (ECTS), rather than the Credit  
91 Accumulation and Transfer Scheme (CATS).

93 Professor Doug King (visiting Professor at the University of Bath), in a report to the  
94 Royal Academy of Engineering (King 2010), suggests that in order to properly address  
95 sustainability in the built environment, professionals with a fundamental understanding  
96 of building engineering physics are needed to limit energy use while achieving desired  
97 levels of environmental performance.

98         However, building engineering physics is not taught widely within undergradu-  
99 ate degrees in the UK and there are just three MEng degree courses in the UK that are  
100 accredited by the Chartered Institute of Building Services Engineers (CIBSE 2013)  
101 which meet the Engineering Council requirements for Chartered Status. Additionally,  
102 the Joint Board of Moderators (which combines the Institution of Civil Engineers, the  
103 Institution of Structural Engineers, the Chartered Institution of Highways and Transpor-  
104 tation and the Institute of Highway Engineers to accredit degree programs) requires stu-  
105 dents of structural engineering to have only an awareness of building physics (JBM  
106 2013) .

107         Within the Department of Architecture and Civil Engineering, the taught unit  
108 ‘Built Environment 1’, undertaken in the first semester of first year, is dedicated to en-  
109 ergy use in buildings, focusing on a fundamental understanding of energy flows and  
110 building physics. This is critically important and is therefore undertaken as soon as pos-  
111 sible.

112         The unit allows students to undertake basic physics calculations to inform deci-  
113 sions about building orientation, envelope materiality and construction to achieve a de-  
114 sirable internal environment. This process requires a degree of iteration and demonstra-  
115 tion of how design changes influence the internal environment, and subsequent energy

116 use. To supplement this, the students' design repertoire is enhanced through a range of  
117 case studies focussing on both best practice and common mistakes.

### 118 *Assessment and adaptations for sustainability*

119 Within the broader context of a unit focusing on the fundamentals of structural design,  
120 coursework is used to investigate how design can influence environmental performance.  
121 Every first year student analyses a building on the University of Bath campus by con-  
122 sidering the architecture (does the intent work, how is the space used by inhabitants,  
123 what is the circulation like); the structure (system used, materials, potential for recy-  
124 cling, evidence of sustainable design); and the building environmental performance  
125 (lighting, ventilation, acoustics, thermal comfort). Students must sketch cross-sections  
126 and an internal view showing what the building is like to use. They are encouraged to  
127 touch radiators, look for mould, comment on the air temperature, and to talk to the  
128 building users.

129 Suddenly structural design is much more than strength and stiffness. The  
130 coursework also requires an assessment of the building against modern sustainability  
131 criteria. Aside from the newer buildings on the University of Bath campus, most per-  
132 form badly (much of the campus was built in the 1960s). Finally, suggestions are made  
133 as to how the building could be adapted to make it more sustainable and all of this in-  
134 formation is presented on a single A3 sheet. Peer review of each student's work in the  
135 form of a 'critique' allows the students to learn from each other.

136 Peer review forms an important part of first year work. This method of assess-  
137 ment helps the students to better understand the importance of good communication in  
138 engineering. A Water Tower design project takes up this concept. Working in groups,  
139 the students must design a water tower within pre-defined material use constraints. The  
140 design packs are then distributed so that each design group builds the structure designed

141 by a different group. The importance of clear communication is then immediately ap-  
142 parent, and each constructing group is able to provide useful feedback to the original  
143 design group as they have all undertaken both sides of the process.

#### 144 *Material choices*

145 Measuring carbon can drive the ways in which products are specified and used in con-  
146 struction. However, considering operational efficiency but not embodied energy could  
147 result in solutions that perform well in their lifespan, but need replacing often and add  
148 significantly to total embodied energy and emissions (Sturgis and Roberts 2010).

149 As the proportion of whole life energy taken by operational energy in the built  
150 environment falls, so the importance of limiting embodied energy rises. Sturgis and  
151 Roberts (2010) also conclude that as much as 60% of whole life carbon could be ac-  
152 counted for in embodied energy, and some analyses suggest that by 2050 improved en-  
153 ergy efficiency could see 90% of whole life emissions arising from embodied energy  
154 (Figure 3).

155 Material choices, therefore, require consideration of much more than just me-  
156 chanical properties. Resource depletion and scarcity, carbon, and energy use must also  
157 be a part of materials education.

158 Providing a broad knowledge base of innovative material choices is crucial in  
159 this respect. In first year, two-page papers are used as a tool to achieve this. Students  
160 must choose a construction material that is not steel, concrete, timber or masonry, and  
161 consider current and future uses, carbon credentials and general sustainability issues.  
162 They must also, crucially, discuss any opportunities the material presents for carbon re-  
163 ductions. Examples of materials chosen range from rammed earth to cardboard, and  
164 from glass to strawbales.

165           Every student then reads and grades every other paper to provide a process of  
166 knowledge sharing and peer review that gives the entire cohort a feel for the possibili-  
167 ties of non-traditional construction materials.

168 *Summary*

169 First year education provides students with a basic vocabulary in structural design, ar-  
170 chitecture and building engineering physics. This provides the basis for subsequent pro-  
171 jects and discussions, makes them aware of the impingements upon the body that can be  
172 caused by poor building physics, and introduces them to the principal design variables  
173 of the built environment.

174 *Later years*

175 As students progress, the principles that they learnt in first year are reinforced by direct  
176 application to project work and supplementary taught units. In Years 2 and 3, building  
177 engineering physics is developed within two further units.

178           Building Environment 2 (Year 2) builds on the passive design methods intro-  
179 duced in in Year 1 by considering the active control of building environments. Heating,  
180 ventilation, day lighting, fire suppression, and acoustic systems are all considered. Stu-  
181 dents are then able to qualitatively and quantitatively assess environmental control sys-  
182 tems.

183           Building Environment 3 (Year 3) provides a practical application of the previous  
184 two units. Specific topics include low and zero carbon heating system technologies, as-  
185 sessment of occupant thermal comfort, heating degree-days to estimate energy use and  
186 the introduction of Passivhaus design concepts. Alongside these the Department also  
187 runs an annual week-long bespoke Passivhaus course for its students, which prepares  
188 them for the official Passivhaus examination, should they wish to register for it. The ap-

189 plied nature of Building Environment 3 is specifically intended as preparation for the  
190 subsequent design projects and eventual graduate work.

191 In Year 3 a joint engineer-architect project focuses on reducing material use and  
192 constructability, and in Year 4 the 'Basil Spence Project' is fundamentally all about cre-  
193 ating an holistic design which encompasses architecture, structure and building physics  
194 innovation in order to achieve an inspirational low-energy use building.

## 195 **Materials**

196 Embedding materials into all aspects of teaching allows students to link their material  
197 choices to scarcity, carbon, future proofing and reuse. This feeds directly into design  
198 projects where carbon counting is used as one tool in the assessment of design deci-  
199 sions, helping to demonstrate the importance of material choices for sustainable design.  
200 This is quite different to more conventional materials teaching that may consider only  
201 chemical composition, structural properties and financial cost.

202 Beyond undergraduate programs, post-graduate taught courses must also provide  
203 materials teaching. Within the MSc in Civil Engineering: Innovative Structural Materi-  
204 als, topics including advanced timber engineering, fibre reinforced polymers, sustaina-  
205 ble concrete technology and glass engineering are introduced.

206 Both undergraduate and post-graduate courses within the Department are linked  
207 to our research activities. This is important for both academics and students and is rein-  
208 forced at an annual departmental research seminar in which all students are invited to  
209 listen to brief research summaries from every academic. This seminar ensures students  
210 are introduced to what we are doing in all areas of sustainability.

## 211 **Research**

212 Research is hugely important for developing taught units and research outcomes are fed

213 directly into taught units. Developing the use of radical, low-carbon building materials  
214 and reinforcement technologies to aid decarbonisation of the built environment is the  
215 key goal of the BRE Centre for Innovative Construction Materials. Material innovations  
216 arising from the centre are strongly embedded in teaching and project work throughout  
217 engineering and architectural degree courses.

218         Increasingly, taught units use computation for design and analysis. The Centre  
219 for Advanced Studies in Architecture (CASA) supports this through its research in par-  
220 ametric design and multiple-objective layout optimisation for complex structures. The  
221 centre works regularly with industry to apply their knowledge to real problems  
222 (Shepherd and Williams 2010), allowing students to see the impact that research can  
223 have on their industrial practice.

224         Research in building physics by the Energy and the Design of the Environment  
225 group focuses on extremely low-energy buildings that meet the requirement for an 80%  
226 cut in emissions by 2050 and the refurbishment of existing structures – both areas that  
227 will be crucially important throughout our students’ careers. Alongside this research is  
228 undertaken into the future of cities and the way interconnections between people and in-  
229 frastructure will be important for transforming the efficiency of energy use, creation and  
230 distribution within urban areas.

## 231 **Industry**

232 Given that higher education is the primary route to entry into the engineering profes-  
233 sion, strong links must be maintained between industry and academia. A tripartite ap-  
234 proach utilising 1) visiting staff, 2) an industrial liaison panel, and 3) our alumni, has  
235 been successful within the Department.

236         The Department employs some 150 visiting tutors each year, all of whom are  
237 chosen in part for their sustainability credentials. As a result, students are exposed to

238 leaders in sustainability from both an academic and industrial perspective. This is evi-  
239 denced by eleven of our visiting Professors and alumni being included in Building De-  
240 sign Magazine's Top 50 Green Leaders (Gilbert 2012).

241 An industrial liaison panel made up of forty members from across the UK pro-  
242 vides input on all aspects of teaching and research programs undertaken within the De-  
243 partment. This input is crucial and must be timely – changes made to a first year degree  
244 course in 2013 will only be seen in the graduates of 2016/17.

245 From these links with industry our students are quickly encouraged to form a  
246 sustainability mindset in their first year of study. They begin to understand that, at least  
247 initially, they will not be judged by the mistakes that they make, and that making mis-  
248 takes is crucial for learning and is far better than not trying at all. Learning from these  
249 mistakes and disseminating best practice is a key tool for sustainability in the built envi-  
250 ronment.

251 The success of our teaching program is reflected in the achievements of our  
252 graduates. Graduate Kai Qu (2010) was named the Institution of Structural Engineers  
253 Young Engineer of the year in 2013 (IStructE 2013), several of our alumni sit on the  
254 Council of the Institution of Structural Engineers, and 2008 graduate Oliver Neve won  
255 the Institution of Civil Engineers Graduate and Student Papers Competition in 2012.  
256 Other alumni successes include the IStructE Supreme Award for Structural Engineering  
257 in 2011 for the Olympic Velodrome, the award for sports or leisure structures, the Da-  
258 vid Alsop Award for sustainability, and the Heritage Award for Building or Infrastruc-  
259 ture Projects (IStructE 2011).

## 260 **Beyond Carbon**

261 Carbon, water and food form the cornerstones of our sustainability agenda in both re-  
262 search and teaching. Each of these aspects is covered in our current teaching portfolio,

263 with relative importance changing as new funding and research centres are launched.

264 ***Water***

265 Averaged over a global population, there is sufficient fresh water on the globe for eve-  
266 ryone's future needs (UN 2013), yet such a simplification overlooks the problem of re-  
267 gional water scarcity that affect billions of people (UN 2012). Changes in water policy,  
268 and management in food production, will be required to meet growing demands for wa-  
269 ter resources.

270 Civil Engineers are well versed in the demands of managing and moving water,  
271 giving them the ability to shape global access to water. The technology to do this is  
272 available; getting it into practice will be a question of policy making and political will.

273 Investment in a water quality laboratory is the first step in a new program of re-  
274 search in this field. A dedicated, newly built laboratory within the Department is due to  
275 launch in 2014, with this infrastructure investment being matched by funding for new  
276 research staff positions. A second collaborative project worth £2.5M between the De-  
277 partment of Chemical Engineering and Wessex Water Ltd to set up a 'Water Innovation  
278 and Research Centre' will be launched in 2014. The centre will provide a unique envi-  
279 ronment to conduct water technology and resource management research, and civil en-  
280 gineering academics will be involved.

281 This research, along with inter-departmental collaborations will lead to the  
282 changes to teaching that are required to meet our sustainability challenges to 2050.

283 ***Food***

284 Global populations rising towards 9 billion by 2050 (Chamie 2004), coupled with  
285 changing and increasingly rich diets, is driving up demand for food. Some estimates  
286 suggest that the increase in demand could exceed 50% by 2030 (Zoellick 2008).

287           Global food production could, however, provide everyone with a high calorie  
288 diet – global food production could already provide upwards of 2700 calories per person  
289 per day (FAO 2002). Yet this is not the case as food is wasted, people cannot afford it,  
290 or it is badly distributed.

291           Simply ensuring that global farmers reach their production potential, which  
292 would require no new technologies, could provide a 50% increase in yields (Foley et al.  
293 2011), making the problem of food provision primarily one of management and not sci-  
294 ence.

295           Civil engineers have the capacity to lead in this area, where policy, coupled with  
296 political and social stability, is key. The management of land has analogies with the  
297 management of construction projects, where resources are balanced with cost over time  
298 to ensure the desired end result is achieved. These skills are taught across the curricu-  
299 lum in ‘Construction Management’ and are transferrable into wider fields, such as food  
300 and land management.

301           Stronger regulation and government policy is required in many countries to pro-  
302 vide a global food network with robustness against economic events and climate  
303 change. Increasing food prices has been closely linked with civil unrest after the food  
304 crises of 2008 and 2010 (Bellemare 2012).

305           Although the period 2050-2080 may not be as productive as 1950-1980 (Fraser  
306 2013), this does not necessarily imply that food will be more scarce than it is today. Ra-  
307 ther, a change in the way that food is dealt with will be required. Having the solutions  
308 means that policy makers need support to make the decisions that are necessary.

309           With research in carbon and water well underway, the next big issue for Civil  
310 Engineers will be in food. This is fundamentally a Civil Engineering problem, as seen in  
311 work by Norton and Lane (2012) and Shrivastava (2003). Its solution will come from

312 land management and international government policy, informed by the research-led  
313 teaching in food, water and waste management of our future Civil Engineers.

### 314 ***Policy***

315 Both food and water, the big global issues after carbon, require strong leadership and  
316 management to implement many of the technological revolutions that have been availa-  
317 ble for some decades.

318         Within hydraulics, our teaching already includes water management policy as a  
319 core topic. Understanding global differences in water policy is crucial if the challenges  
320 outlined above are to be met.

321         However, weak political structures can mean that decisions are never made, or  
322 that money is wasted on projects that do not provide long-term benefits. Many decisions  
323 ultimately have little to do with money, and more to do with weak leadership in policy  
324 making that means decisions are not made (because no-one has the support or  
325 knowledge to make the decision).

326         These challenges are demonstrated in Tanzania, where despite water resources  
327 of 2300m<sup>3</sup> per capita (Frenken 2005) widespread water scarcity exists due to low water  
328 storage capacity, variations in rainfall distribution and intensity, and institutional weak-  
329 nesses in water management (MKUKUTA 2007).

330         This makes the provision of water and construction management education cru-  
331 cial. Students are shown how important it is to get involved in policy-making decisions;  
332 and this means that they must become leaders.

### 333 **Assessment**

334 Assessing engineering degrees can lead to contradictions in practice. Students are  
335 judged by exam results, but examinations are not what an engineer does. Industrial

336 feedback suggests that on occasion first class students show less skill in industrial set-  
337 tings than some with a third class degree. Such a situation simply shows that degree  
338 classifications can measure the wrong thing.

339         Assessment by closed book examination is one means by which this situation  
340 can arise as such exams often take the form of a memory test rather than assessing fun-  
341 damental understanding. This is pertinent in structural analysis, where a full understand-  
342 ing of the principles adds coherence to subsequent calculations (May and Johnson 2008)  
343 and avoids surface learning effects.

344         Examinations themselves have also changed, with questions now designed to  
345 test an ability to think in a qualitative way being desirable. More traditional mathemati-  
346 cal assessment can then be undertaken as coursework, which better represents the reality  
347 of engineering practice.

348         The future may see examinations becoming the background, rather than front-  
349 line, assessment. This is illustrated in Figure 4 where a proposed unit assessment route  
350 is shown. Assessment by short individual or group projects and workshops (1 hour to 1  
351 day in length) inserted throughout the semester would allow students to demonstrate  
352 their working and practical knowledge of a subject. Assessment of up to 80% of the unit  
353 marks in this way would then be supported by a final examination focusing on their  
354 ability to think around key topics. The key to this approach is that the examination  
355 would have to be passed to progress, but the weighting given to it would be appropriate-  
356 ly low.

357         It is envisaged that such an approach would generate engagement (through  
358 workshop sessions) and a more philosophical outlook of graduates. Under this model of  
359 assessment, a student awarded a first class degree would (it is hoped) graduate as a first  
360 class engineer capable of an holistic approach to sustainable design.

## 361 **Support**

362 The extra-curricular endeavours of students must be supported at all stages. Providing  
363 opportunities and financial support to explore ideas is key to this. Since 1998 The Hap-  
364 pold Trust has supported a travel scholarship for one or two final year students. Modest  
365 financial support (£1000) has achieved great things and provided real benefits to our  
366 graduating students.

367 Recent projects include:

- 368 • 2013 – When the Levee Breaks: Dealing with the aftermath of storms in the  
369 USA (Jack Ford)
- 370 • 2012 – Structural contradictions in the UAE: from essential to extravagant  
371 (Roseanne Boyce and Elizabeth Smith)
- 372 • 2011 – Engineering the Trans-Siberian railway, and seismic design in Japan  
373 (Matthew Bouloux)
- 374 • 2010 – Construction of mountain refuges in the Pyrenees (Robert Foster)

375 Engineers Without Borders has a strong program of activities within the De-  
376 partment. Students who undertake these opportunities tend to learn more than they pro-  
377 vide to the people they visit and this is a key reason why support is provided.

## 378 **Conclusions**

379 This paper has shown how a blended delivery of engineering, architecture, building  
380 physics and the freedom to experiment can provide a basis for sustainable design in the  
381 built environment. Introducing a way of thinking in first year that is then reinforced in  
382 subsequent teaching and project work has been key to the success of this approach at  
383 Bath.

384           This approach is not the only (or necessarily the best) way to approach teaching  
385 engineering sustainability. Our annual reviews of teaching mean that the course content  
386 is able to change quickly, if needed. This paper does not presume to suggest that we  
387 have done everything right, but aims to demonstrate the success we have achieved with  
388 the methods we have used. It should act as a discussion point for engineering education.

389           A current emphasis on building environmental physics is set to increase in the  
390 future and this should be common across all civil engineering degrees. More universi-  
391 ties need to get building physicists involved in their teaching and research, with the pos-  
392 sibility for future MEng level degree programs in Building Engineering Physics as a  
393 third strand to the ‘classic’ architecture and civil engineering programs.

394           Design for use and post occupancy need to be considered more in practice, and  
395 this means taught design units must include these issues. This should be matched with  
396 appropriate examination techniques that assess students’ ability to think rather than to  
397 do sums.

398           It is clear that academia and industry have a lot to learn from each other and the  
399 role of our industrial liaison panel has been important in developing the degree program  
400 that is run today.

401           The importance of legislation in all of this, associated with sustainability is key  
402 to achieving change in the built environment and will be driven forwards through edu-  
403 cation.

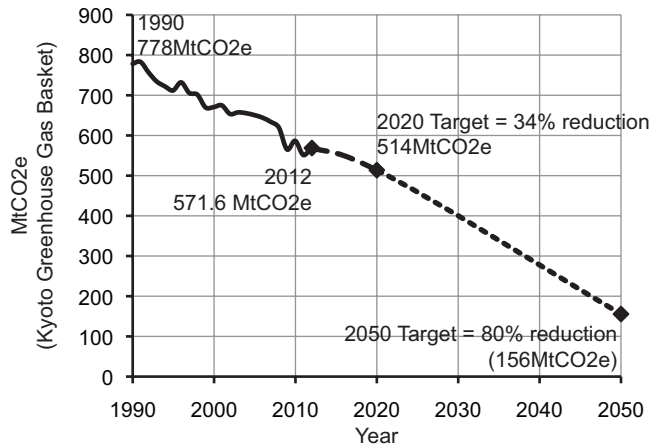

404           Finally, all of these aspects have been achieved whilst retaining 100% positive  
405 student feedback across all graduate program areas (HEFCE 2012). Challenging and  
406 motivating students with high quality teaching and assessment methods is key to con-  
407 tinuing this.
